Analysis of Water, The Chemical and Biological, by T. H. Pearmain and C. G. Moor, M.A., 503, 531, 557, 585, 612, 640, 661
Analytical Anomalies, 407
Animal Refuse, The Disposal of, by Dr. Philip Boobbyer, M.O.H., 67
Annato in Milk, The Detection of, 44 of Supp., June
Annual Reports, Annotations from, 231 367, 400, 426, 458, 558, 648
Anomaly, A Strange, 62
Antiseptics in the Preservation of Meat, 30 of Supp., April

BACTERIOLOGICAL *v.* Chemical Examination of Water, 619
Barbers' Shops, Insanitary, 44
Bedroom Sanitation, 72
Beer Question, The Pure, 43 of Supp., June
Beer, The Dangers of Drugged, 28 of Supp., April
Beverages, Beneficial and Otherwise, 35 of Supp., May
Birstall Sewage Disposal Works, 368
Bombay, The Renovation of, 237
Book Notes and Reviews (*see* Reviews)
Books, The Disinfection of, 14 of Supp., Feb.
Bread the World Over, 13 of Supp., Feb.

CEMENT, Lime, Mortar and: Their Composition and Analysis, by W. J. Dibdin, F.I.C., F.C.S., 445, 473, 500, 529, 559, 614, 663
Cheese, Interesting Facts about, 35 of Supp., May
Chinosol, 117
Cigarette Smoking Injurious? Is, 42
Cistern, A New Form of, 454
Cistern, A Sanitary, at Last, 92
Coffee, Medicinal Uses of, 15 of Supp., Feb.
COMING MUNICIPAL MEN:—
Brown, Mr. Reginald, 537
Latham, Mr. Frank, 257
Kieser, Mr. William H. G., 621
Competitions, 25, 53, 129, 158, 185, 214, 241, 270, 297, 326, 354, 382, 410, 494, 577, 606, 634, 682
Condensed Milk: Its Composition and Valuation, by C. G. Moor, 36 of Supp., May
Consumption: Suggestion to Sanitary Authorities, 647
Contracts Open, 24, 52, 80, 102, 129, 157, 185, 213, 240, 270, 296, 326, 354, 382, 410, 438, 466, 494, 522, 549, 577, 606, 633, 654, 681
CORRESPONDENCE:—
A Disclaimer, 435
An American Physician on Premature Burial, 519
A Royal Commission on Sewage Disposal, 293
Bovine Tuberculosis, 463
Cost of Bacteria Systems, 322
Correspondence—*cont.*
Disinfection of Rooms, 406
Leeds Sanitary Congress—Surcharge of Delegates' Expenses, 21
London Drains, 348
Our Prison System, 491
Relative Cost of Works of Sewage Disposal, 183, 266, 320, 347
Royal Commission on Sewage Disposal, 293
Salford Sewage Experiments, 377
Sewage Disposal and Wheat Growing, 378, 406
Sewage Purification, 322, 348, 406
The Infectious Diseases Notification Act, 1889, 125
The Pure Beer Question, 679
The Sanitation of Cowsheds, Dairies, and Milkshops, 78
The Vaccine Marks Theory, 126
Cowsheds, Dairies, and Milkshops. The Sanitation of, by Dr. James R. Kaye, 41
Crown Privileges, 413

DAIRYMEN and their Servants, 38 of Supp., May
Damp Walls, The Treatment of, 455
Diarrhœa, by Alfred Hill, M.D., 69
Dietetic, A New, 71
Diet for Consumptives, 30 of Supp, April
Diet in the Treatment of Inebriety, 360
Diet of Dyspeptics, The, 31 of Supp., April
Diet of Prospective Mothers, 30 of Supp., April
Digestion of Food, How the Saliva assists the, 34 of Supp., May
Diphtheria at Puttenham, 17
Diploma in Public Health, The Value of a, 595
Disease, The Prevention of, 228
Disinfection by Chlorine Compounds, Recent, by S. Rideal D.Sc. (Lond.) 587
Disinfection in Paris, Progress of, 595
Domestic Buildings, The Sanitation of, by Frank Latham, C.E., M. San. Inst., 6, 35, 60, 89, 109, 139, 166, 195, 223, 252, 278, 306, 364, 389, 418, 447, 477, 535
Domestic Refuse Destructor, A, 200
Drainage, Some Examples of Scamped, by Dr. W. L. Hunter, M.A., M.O.H., 452
Drains and Typhoid, 11
Drain Traps, Efficient, by Dr. Herbert Jones, 593
Drinking Fountain, A Sanitary, 480
Drugged Beer, The Dangers of, 28 of Supp. April

EDINBURGH, The Social and Sanitary Society of, 118
Eggs as a Food, The Value of, 14 of Supp., Feb.
Elementary Schools, The Closing of, in Times of Epidemic, 176
Epidemiological Society, 366
Exeter Sewage Scheme, The Local Government Board and the, 644
Exhibition, The Medical and Surgical, 599

FACTORY, A Sanitary Sausage, 4 of Supp., Jan.
Farm Buildings, Sanitary, by Louis Hanks, A.S.I., 37
Feed-water, The Purification of, 71
Fever, From whence came the, to Lynn, 169, 196
Filters, Biological Sewage, 11
Flooring in Public and Private Buildings, Insanitary, 248
Food Adulteration Frauds in France, 33 of Supp., May
Food and Drugs Bill, 1897, Sale of, 12 of Supp., Feb.
Food and Finance, 38 of Supp., May
Food and Health, What People should Avoid, 93
Food and the State of Health, 3 of Supp., Jan.
Food Poisoning, 14 of Supp., Feb.
Food Standards, 14 of Supp., Feb.
FOODSTUFFS UNDER SCRUTINY:—
"D C.L." Malt Extract, 17 of Supp., March
Edwards' Humanised Condensed Milk, 41 of Supp., June
Hay's Food for Infants and Invalids, 17 of Supp., March
Hay's Frumentine, 1 of Supp., Jan.
"Index" Rolled Oats, 1 of Supp., Jan.
Koumiss, 33 of Supp., May
Lipton's Extract of Beef, 25 of Supp., April
Oxine, 10 of Supp., Feb.
"Sap" Brand Humanised Milk, 33 of Supp., May
Vejos, 25 of Supp., April
Foods, The Need of Fat, 6 of Supp., Jan.

GAS Burner for Street and Domestic Lighting, A New, 540
General News, 18, 45, 73, 95, 121, 150, 180, 208, 232, 261, 290, 317, 344, 373, 403, 432, 459, 487, 515, 542, 570, 600, 626, 649, 675
Glasgow New Sanitary Chambers, 313
Gymnasia, Public, by Guy C. Rothery, 9

"HALF-TIMERS," 665
Hampstead Public Baths, 487
Healthy Dwellings and Sanitary Towns, 568
Healthy Towns and Villages, 202

NOTICES.

ANNUAL SUBSCRIPTIONS. — The Annual Subscription to "The Sanitary Record," paid in advance, is 10*s. This includes postage, and a Copy of the Diary, post free.*

SUBSCRIBERS RESIDING in SCOTLAND and IRELAND are requested to pay by P.O. and NOT *by cheque. If cheques* BE *sent they must be drawn for* 10*s. 6d*

NOTICE TO FOREIGN SUBSCRIBERS. — The Yearly Subscription for the Colonies and Abroad is 13*s. 6d.*

MSS. cannot be returned unless accompanied by a stamped directed envelope.

Advertisements cannot be inserted unless received before Four o'clock on the TUESDAY of each week.

All communications should be addressed to the EDITOR, at 5, *FETTER LANE, London, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, Ld.*

THE

Sanitary Record,

JANUARY 7, 1898.

PAST AND FUTURE.

Once more the whirligig of time has brought round the commencement of a new volume of the Sanitary Record, and on the threshold of another year we are again constrained to dilate upon the past, and discuss the future. Both, we are glad to say, are pleasant tasks. Behind us is a record year in every sense of the word, while ahead the prospect is bright with the promise of even better and greater things.

Two occurrences may fitly claim to have preceded in our retrospect, viz., the publication of the Dibdin series of articles on "The Purification of Sewage and Water," and the Imperial Victorian Exhibition at the Crystal Palace. Though totally dissimilar, both have had no small share in strengthening our position. The "Food and Health" supplements, too, have been notable factors in the past year's success.

In a general way we owe much to the individual efforts of our readers of all classes, and we take the present opportunity of thanking them one and all for their cheering and disinterested help. We think it will be generally admitted that we have kept our promise to study and promote the interests of all classes interested in public health matters without undue distinction. At all events, such has been our endeavour, and such is the attitude we mean to maintain in the future.

Our programme for the year that is ahead is too comprehensive to enter into fully, but our readers may rest assured that it will not be found wanting in those important details which constitute the features of an up-to-date journal. Many of the best writers on public health matters have been commissioned to give the results of their life studies in our columns, and Mr. Dibdin will continue to communicate to us the latest phases of his work in the form of special articles, the first of which appears in our present issue. Mr. W. H. Maxwell will carry his "Notes on Practical Sanitary Science" through some highly interesting chapters to a successful conclusion; our "Notes and Queries" will, as heretofore, assist our readers in solving the problems which from time to time arise upon various topics, and as it is our desire to extend this feature, we solicit the fullest possible use of its benefits. Mr. F. Latham, it will be noted, commences in the present issue, a series of practical papers on "The Sanitation of Domestic Buildings;" and we have made arrangements with Mr. C. G. Moor, M.A., F.I.C., of the State Laboratory of Medicine, King's College, to contribute early in the year a series of articles on "Hygiene." Medical Officers of Health all over the country will, as previously, communicate notes and comments of interest, and Sanitary Inspectors will find greater prominence than ever given to the doings of their organisations in whatever part of the country they may exist. Important developments will be made in other features, but what these are, must, for obvious reasons, be kept in abeyance. Our readers may take it for granted that we are keenly alive to their needs, and that what so many of them have been pleased to comment upon eulogistically is merely an earnest of what we intend to do during the year that is before us.

Notes.

The year that has just closed has been one of exceptional prosperity for the whole of the United Kingdom, the volume of trade exceeding what has been recorded for many years past. In the working classes especially such a season of prosperity spells increased comfort in the home, and probably greater attention to hygienic requirements. Indications of this may be seen in various trade returns. In the building trade, for example, which

has enjoyed a period of phenomenal activity during the last twelve months, it is very gratifying to observe that the principal increase has been in tenements of two-roomed houses, which is a sign that superior house accommodation is in growing demand among the masses of the population. The danger at such a time of building enterprise is that builders, in their haste to take advantage of the wave of prosperity and to get their contracts completed with profit to themselves, may put out an inferior class of work; and the recognition of this inevitable temptation must therefore call for increased vigilance from Sanitary Inspectors in the supervision of all work brought under their notice.

Among the recipients of the New Year Honours gazetted last week, we find the names of three medical men of considerable eminence—Dr. Batty Tuke, President of the Royal College of Physicians, Edinburgh; Dr. Struthers, President of the Royal College of Surgeons, Edinburgh; and Dr. Gairdner, Professor of Medicine in the University of Glasgow. The name of Dr. Gairdner is of especial interest to all who are interested in Health. In 1862, the year in which he received the appointment to his present chair, he published a volume entitled, "Public Health in relation to Air and Water," the record of the first course of lectures on sanitation ever delivered in Scotland. The introduction of this volume to the notice of Mr. Ure, then Convener of the Health Committee of the city of Glasgow, and afterwards Lord Provost of the city, led to his seeking the co-operation of Professor Gairdner in carrying out a scheme which he had framed for the establishment of what has since become the Health Department of the city, with the result that Professor Gairdner was appointed the first Medical Officer of Health of Glasgow, and held that post for nine years.

In the discharge of his duties in that capacity, Professor Gairdner was called upon to deal with several severe epidemics. In connection with the threatened visitation of cholera in 1866, as well as with various outbreaks of fever in other years, he made a systematic investigation of the conditions of the tenement houses and slums of the more densely-populated parts of Glasgow. He also visited Paris, with the view of examining the improvements which had been carried out by the Emperor in the French capital; and it was in part owing to the experience gained during that visit, in addition to his previous experience at home, that the great revolution in the sanitation of Glasgow effected by the first Improvement Act was brought about. Professor Gairdner may, therefore, in a sense be congratulated as having been one of the fathers of sanitation in Scotland, and his new-found dignity of K.C.B. is a well-deserved recognition of the services he has rendered to humanity during a long and useful career.

One other New Year Honour falls to be noted here. Sir Thomas Lipton's knighthood may be taken to be a tribute not merely to an exceptionally successful business career, but in part no doubt to the princely use he has made of his wealth, notably in his contribution of £25,000 to the Princess of Wales' Jubilee Dinner Fund, and in relieving the congested districts of Ireland by his large purchases of the produce of the impoverished tenantry. At the present time considerable interest attaches to the scheme which Sir Thomas is understood to be maturing, for the establishment of restaurants all over London, for the benefit of the poorer classes. He proposes to expend about a sum of £100,000 on these restaurants, where the poor may be able to get substantial and wholesome meals at a very low figure; for instance, he calculates that a good dinner should be supplied for about 4d., or 4½d.—and where they may also be able to enjoy a little reading, and other profitable recreations. It is intended that these institutions shall be scattered in all parts of London where there is a large industrial population; and it is of the essence of the scheme that they should be made self-supporting. The plan has already received the support of many influential persons in high position, and it is believed that it will shortly assume practical shape.

The conception of these institutions is somewhat similar to that of the Rowton Houses Company, of which Lord Rowton is the chairman and moving spirit, and which aims at providing poor men's hotels or clubs, where working men may not only dine and pass an evening, but where they may sleep and enjoy a good bath at any hour. The Rowton Company has been pretty well before the public of late, first on account of its successful fight with the London County Council, who claimed that their consent was necessary under the Building Act of 1894, to the erection of these homes, and next because of the opening the other day of the newest and largest of the Rowton Houses, with accommodation for 800 men. They are altogether wonderful establishments, these Houses, and marvellously cheap. A man can occupy an excellent room for 6d. a night, and it is calculated that he can live there in considerable comfort for 10s. a week.

But to the sanitarian, one of their chief merits is the facilities they afford to a poor man for getting a good wash. There are many men who do not belong in strictness to the working classes, who have seen happier circumstances, but who, having come down in the world, are compelled to forego many of the comforts which to them are almost as the necessaries of life. To such men the inability to procure hot water and a bath when they wish, to be compelled to live in dirt, would make all the difference between comfort and misery, and to them the Rowton Houses offer an inexpressible boon. They can there enjoy, at a moderate cost, and in pleasant surroundings, many of the comforts which are usually supposed to be only within the reach of the well-to-do classes, and they can make sure, at all events, of living in cleanliness and health. Such institutions as the Rowton Houses have already erected and are still erecting in various parts of London, and as Sir Thomas Lipton contemplates establishing, are a marvellous feature of the age, and one which should do much to elevate the poorer classes, and raise a standard of comfort and cleanliness which cannot fail to have far-reaching results. And perhaps the most remarkable thing about them is that they can be conducted as successful commercial ventures, and not merely as philanthropic and charitable enterprises.

INSTRUCTION by means of popular lectures is comparatively a modern idea; and although it is not exactly an ideal educational instrument, it often stimulates the hearers, and induces them to seek for fuller and more adequate information elsewhere. Among the many topics chosen by public lecturers, we are glad to see that there is a growing tendency to treat of what have come to be known as "social subjects," and that so many of these bear on questions connected with the public health. The report of one of these lectures is before us, the subject being "The Houses of the Poor," and it will readily be admitted that there are few questions that have a more important bearing on the health of the community than how to provide suitable and adequate dwelling accommodation for working people. The history of nearly every epidemic has shown that the disease has broken out and raged with greatest fury in those quarters of a town or city in which the poorest class have dwelt, for such dwellings are most frequently insanitary, both in their construction and in their surroundings. The poor people have often, however, no choice; and the burden must lie on the wealthier members of the community to see that their less fortunate neighbours are decently and healthily housed.

THE reading of a lecture on "Dairy Sanitation" is apt to leave on the mind a feeling of vague wonder how it is that any of us are alive. For we all use milk in one form or another; and it seems so difficult to keep cow-houses and byres free from contamination, that it might well be matter for surprise that tuberculosis and diphtheria and scarlet fever are not circulated with every round of the milk carts. And yet the efforts of Medical Officers of Health and of Sanitary Inspectors have been so successful that there are many cow-houses which are quite above suspicion. This means, of course, not only careful inspection, but a very large and constant amount of conscientious supervision on the part of the dairy keepers. It implies the keeping of the byre at the right temperature, together with an adequate degree of ventilation—two conditions not always easy to combine; the admission of an abundance of sunlight, which is specially inimical to the welfare of bacteria; the due separation of the milk-house from the byre, from dwelling-houses, and from dungsteads; the most scrupulous personal cleanliness in the dairy operations, and the greater care in the cleansing of the milk-vessels. The task is not a simple or a light one, but experience has shown that it can be accomplished, while yet the dairy business is made a sufficiently profitable one.

LORD SALISBURY'S recent pronouncement on the subject of London municipal government has been followed up by action that may result in an important readjustment of several of the existing City administrations. The Moderate party in the County Council are moving in the matter, and are showing that they are very much in earnest in desiring a change. Their aim is to persuade the Prime Minister to confer upon a number of the more important metropolitan parishes, whose affairs are at present administered merely by local Vestries, the dignity of incorporation. At a meeting held recently of the representatives of these parishes—including Westminster, St. Marleybone, St. Pancras, Kensington, Lambeth, Chelsea, Hampstead, Paddington, St. James's, Deptford, and Hammersmith—a resolution was adopted to present a memorial to the Prime Minister and the Duke of Devonshire which may have momentous consequences.

THE memorial sets forth that the parishes in question represent in the aggregate a population of 1,379,876, and a rateable value of £12,296,751. Men who come before the Government with such a backing may reasonably think that they have a fair claim to get a hearing; and they may justifiably believe that in such a position they have a right to urge, as the memorial does urge, "the introduction of a Bill to create metropolitan municipalities of dignity and importance, with powers to undertake and perform municipal duties; subject, of course, to the peculiar circumstances of the metropolis, which must reserve to the existing central Authorities the management and control of such matters as affect the whole of London as a county." The thought embodied in this memorial seems to correspond, fairly enough, with the ideal of a municipality sketched the other day by Mr. Chamberlain, which should consist of men known to the electors, and which should be sufficiently in touch with them and with their requirements and desires, to be able to meet these in the most effective way possible. The difficulty with the Government, of course, is to draw the line with sufficient accuracy between over-centralisation and undue delegation of powers; but in a huge community like ours the danger lies rather in the former direction than in the latter. The Prime Minister has agreed to receive a deputation on January 20th.

SIR JOHN HUTTON had a congenial task on Saturday last when delivering his presidential address to the Sanitary Inspectors' Association at Carpenters' Hall. As a past chairman of the most important municipal body in the world, he could speak with authority on the progress made in London's Health Department in recent years. In one sense the figures given by him are simply appalling If in less than a century London has quadrupled itself, we may well shrink from trying to estimate what the progress is to be in future years. Again, the effect of modern methods upon the longevity of the race was well illustrated by the comparison of the death-rate two centuries and a-half ago and that prevailing in the metropolis to-day. In 1660 the inhabitants died at the rate of 80 per 1000, but in 1896, with a population verging on four and a-half millions, only 18·9 per 1000 deaths were recorded. We thoroughly endorse Sir John's remarks on the necessity of maintaining a high status among the ranks of Sanitary Inspectors. But to do this requires something more than the appointment of an Examination Board, excellent as that may be in itself. If men are to be expected to put in good and conscientious work in carrying out the duties of their office, a substantial advance must be made in the remuneration of the Sanitary Inspector. To expect a high standard among those who do not value their services at more than £50 or £60 a year, is looking for the impossible; and the sooner our Local Authorities realise this the better. With a "living" salary and more graceful acknowledgment of his services, the status of the Inspector would soon attain a higher level.

Last Saturday the Maidstone Town Council received a report from Dr. Washbourne and Mr. Adams, who have carried out a thorough analysis of some water obtained from the Tutsham spring, the pollution of which is generally supposed to be the cause of the typhoid epidemic. These gentlemen state that it is a debateable question whether it is possible in the present state of our knowledge to demonstrate the presence of the typhoid bacillus in water contaminated with typhoid material. Most of the cases in which typhoid bacilli are stated to have been found in drinking water occurred at a time when the tests available for distinguishing the typhoid bacillus from bacteria were insufficient. The difficulty of recognising the typhoid bacillus is so great, the analysts state, that no importance can be attached to the failure of discovering the typhoid bacillus in water suspected of being the cause of an epidemic. The contents of the analysis occasioned considerable surprise in Maidstone. The analysts, however, explain that in the absence of the typhoid bacillus in the samples of water taken from the Tutsham spring (supposed source of epidemic) may be accounted for by the fact that the samples were not taken earlier. Although they discovered no typhoid bacilli, they found conclusive evidence of contamination with animal excreta.

The first move taken by the Mayor of Greater New York on his assumption of office is not calculated to inspire confidence in the minds of the advocates of good and pure government. To remove, at one stroke, the heads of fifty departments, and replace men with inexperienced, and therefore inefficient men, does not bode well for the administrative work of the municipality. It is "popular" government carried to the very worst extreme. The dominating idea of these "bosses" will not be the well-being of the people, not the abolition of public nuisances, nor the sweeping away of insanitary and dilapidated property; but keeping themselves in the good books of Tammany Hall. And what is true of the "bosses" is equally applicable to every grade of the service. Each man will be simply working for his own ends. He will know that the same "popular" vote that has given him a position, may take it from him at the end of four years, and it is only human nature that he should do his best to make the most of his opportunity. The whole system of "party government" as carried out in America is a burning disgrace to a great nation. It opens every door possible for bribery and corruption of the vilest and most discreditable type. The mystery is why the people should permit themselves to be the tools of these place-seekers and partymongers. To think that the health of a great city should be placed in the keeping of men utterly devoid of any other qualification than that of being "Democrat" or "Republican" passes the comprehension of all right-thinking men and women.

The Health of London is satisfactory, if we accept the interesting report of Dr. Shirley Murphy, the Medical Officer of the London County Council. The population of the Administrative County of London is estimated at 4,443,311; and of this number Islington contributes the lion's share with a population of 337,639; Lambeth, Camberwell, and St. Pancras following at a respectable distance. In 1896 it would appear that London had a lower death-rate—18·1 per 1000—than that of Manchester, Liverpool, Birmingham, Leeds, Sheffield, Hull, and Salford. And the healthiest district in the metropolis is Islington, to the north of the Thames, with a death-rate of 15·6 per 1000. This is eminently satisfactory, as Islington is also the most populous in "the great village." Details are given of outbreaks of infectious diseases on milk-shop premises, which were summarily dealt with. After all, 256 cases of disease out of 21,284 inspections show that the Dairy and Milkshop Orders are fairly well administered in the county of London.

"Watering milk" is the modern equivalent of "the cow with the iron tail," which greatly affects the quality of the fluid supplied to the patients in our London hospitals. It is really too bad to deprive needy patients of wholesome nourishment by dilution with water. Some wholesale London milkmen profess to "sell milk as the cow gives it," but the *Lancet* finds that to be erroneous. Eleven samples of milk supplied to hospitals have just been examined; seven were of good average quality, two were of indifferent quality, and two were decidedly poor and in all probability diluted. Our contemporary is of opinion that our great charitable institutions should be protected against this watering process, and for this purpose the Government should strengthen the hands of the Inspectors under the Sale of Foods Act. The best plan would be to take a sample from every can as it arrives at the hospitals from the stations; and then make an example of the man who dares to rob the sick poor of "milk as the cow *gives it*."

Explosives are occasionally employed to clear away obstructions in the course of drainage and sewerage works; and the late Mr. Alfred Nobel's dynamite is frequently utilised as the agent. Out of the fortune the inventor made he has left a portion for "the benefit of humanity." After various bequests, the capital of the whole of the remaining realisable property is to form a fund the interest from which is "to be annually divided in five prizes to those who during the previous year have done most for the benefit of humanity." Sanitarians may be interested in the departments of natural physiology, philosophy, chemistry, or medicine, and the prize-winners will be those who have made the most important discovery or inventions, or improvements in either of these branches. The fortune left by Mr. Nobel is just under half a million.

Sewage outfall works are in course of construction in Cheshire for the Corporation of Stockport, and in the process of excavation a unique bog oak was discovered, weighing about 40 tons. This grand fossilised trunk, with two branches, is an exceptionally fine specimen, exceeding in dimensions any oak now growing in this country; and its quality, beauty of colour and grain make it unique, as there is sufficient material to furnish a town hall or other public building. The Corporation proposed to blow it up with dynamite, but the townsfolk objected. There is no doubt that a number of enthusiastic antiquarians will defray the expense of excavation, in order that this mighty oak of the centuries may be preserved as a historic specimen of the treasures of the earth.

AMMONIACAL NITROGEN IN SEWAGE AND EFFLUENTS.

By W. J. Dibdin, F.I.C., F.C.S., &c.

The question having been raised as to the value of certain bacterial methods of sewage treatment as judged by the analytical results which have been published from time to time, it will be of value to discuss the question in full in order that the point may be set at rest, as unless this is thoroughly done it will continue to be objected by captious critics that the system is uncertain, and therefore unreliable, despite the fact that a satisfactory degree of efficiency is attained.

I will first set out the results of analyses by various chemists of the sewage and tank effluent obtained by the process known as the septic tank system. The following table will indicate these very clearly :—

Date—1896.	Chemist.	Free ammonia. Sewage.	Tank effluent.	Difference. p c.
Oct. 26th and 27th	Perkins	4·5	7·5	+ 66
Nov. 3rd and 4th	Rideal	3·6	4·9	+ 33
Nov. 3rd to 15th	Dupré	3·6	5·6	+ 55
Nov. 13th and 14th	Rideal	8·5	11·2	+ 32
1897.				
April 5th to 9th	Dibdin and Thudichum	4·3	4·6	+ 7
May 23rd to June 8th	Moore	4·4	2·8	− 36
June 17th to 22nd	Dibdin and Thudichum	3·5	2·2	− 40

Unfortunately the temperature of the sewage does not appear to have been observed in all cases, this factor having evidently been considered as unimportant, and therefore overlooked; but it may safely be assumed that the temperature of the sewage would follow the season, and I have, therefore, set out the analyses in order of date, commencing with the period when the process was first started.

It is a fact well known to all bacteriologists that microbic action is all but dormant when the temperature to which the organisms are exposed approaches the freezing point, but that it gradually increases as the temperature rises, and thus it is that when it is desired to promote bacterial development the inoculated materials are placed in a chamber which is kept at the constant temperature of 21·5 deg. Cent., or 71 deg. Fah. nearly, with the result that in a day or two the growth of the colonies formed from the single germs will often be so great as to liquefy the whole of the cultivating medium, whereas at a temperature below 40 deg. Fah. they might have been kept for weeks before such a result would have been attained.

In a septic tank, exposed to all the variations of climate and receiving sewage at corresponding variations of temperature, a similar condition of things might be expected, and such is indeed the case. During the colder weather the organisms, or certain of them, can perform a certain amount of work in peptonising the solid organic matters, but not always to the full extent, while the nitrifying, or oxidising organisms, are in a sluggish condition and incapable of effecting the further change of the ammoniacal nitrogen or "free ammonia," as it is generally called, to a degree comparable with that prevailing at a higher temperature. The result of this action is, therefore, that in the winter and early spring an increase in the quantity of ammonia in solution is observed in the effluent issuing from the tank, whilst during the warm summer months, when the temperature of the sewage is necessarily higher, the ammonia formed by the bacterial action on the nitrogenous ingredients of the sewage is either oxidised into oxides of nitrogen or set free in a gaseous form, and thus a less quantity of ammonia is found in the effluent than in the sewage, and, seemingly, ground is afforded for the objection that contradictory results are obtained by different observers, when those observers make their determinations of the quantity of free ammonia at different periods of the year. This erroneous argument has arisen from the method in which some of the results have been published. Instead of the whole of the details being set out in full, averages of all the observations made at different periods have been given.

Having regard to the final character of the effluent obtained, the point is in reality unimportant, were it not for the fact that on insufficient data, and want of knowledge of the conditions of the problem, criticism is brought into play on a side issue to weaken the definite statements of competent and impartial experimentalists, who, working independently and under different conditions, have naturally obtained results which at first sight appeared to be contradictory to the results of work both by themselves and others.

Over and over again the same sequence of events has occurred, not only in regard to sewage treatment, but with respect to almost every experimental stage through which we have to pass. One of the first things which a student has to learn in connection with scientific work is that when he obtains a certain and definite result, and has proved by all reasonable and proper checks that there was no mistake on his part, he must have the moral courage to adhere to it, never minding the "impossible's," and "can't be's" of those who have not troubled to repeat his experiments, or to understand the conditions relating to it. For a time he may be under a cloud of suspicion as to his capacity; he may receive many a cold shoulder; but he must be deaf, dumb, and blind to all save the definite experimental proof of his error or confirmation of his result.

In the case of bacterial action on crude sewage taking place in a coarse bed, aërated after each discharge of effluent, as in the Sutton system, the presence of atmospheric oxygen was sufficient to ensure such an action that a decrease of ammonia took place, except on two occasions, viz., February 8th and May 17th. On the latter date the action of the bed had been seriously interfered with by overwork, to which it had been purposely subjected for experimental purposes. In the case of the final filtrates from the fine bed, whether at Exeter or at Sutton, we have a very large percentage reduction of free ammonia following the aëration of the beds, together with a considerable development of nitrates, although insufficient to account for the total nitrogen in the original sewage, a large proportion of which undoubtedly escaped in a gaseous form. That this must be so will be evident from the consideration of the fact that while the above remarks apply only to the matters dissolved in the water, there yet remains for discussion the nitrogen in combination with the solid suspended particles. If these are taken at 60 grains per gallon (*vide* Sutton results), of which 30 grains may be reckoned as organic, and the nitrogen on this quantity reckoned at 5 per cent.

(which factor I deduce from numerous determinations on average sewage mud), we have 1·5 grains of organic nitrogen per gallon in the form of solids, which are unaccounted for in the effluent, which, as already shown, contains less total nitrogen in all forms than was present in solution in the original sewage. It is, therefore, evident that as neither this solid nitrogen, as it may be called, nor the total quantity of dissolved nitrogen is accounted for, there must be a loss, and this loss can only, in the light of our present knowledge, have taken place by its conversion into a gaseous form, in which condition it escapes into the atmosphere. The question is one which requires very careful research for its elucidation, and will doubtless shortly receive the attention of those who are fortunate in having the time at their disposal to devote to it, as a complete knowledge of the whole series of changes which take place must result in placing the process of bacterial treatment upon still more definite and firm lines. Fortunately, however, the practical outcome of the position is such, that while we wait for further information, we need not hold our hands in applying the substantial knowledge we now have to the treatment of foul water, and thus to secure for the public benefit the fruits of the work already done.

THE SANITATION OF DOMESTIC BUILDINGS.

By Frank Latham, C.E., M. San. Inst., &c., Assistant Surveyor, Borough of Margate.

CHAPTER I.

INTRODUCTION.

The subject of house drainage is one which demands a greater amount of serious attention than is ordinarily paid to it, this neglect being in many cases the product of ignorance regarding the methods of modern sanitation, and in some instances the result of less excusable influences. That the diseases caused by sewer air and communicated through defective house drains are constantly with us cannot be denied. This condition of things could be ameliorated, if not entirely prevented, and the death-rate reduced, if more earnest thought were given to it; and it is the object of these articles to throw some light upon this important truth, with the hope that it may be of some practical help to those whose health and happiness is bound up in this vital question. Some people are apt to evade sanitary precautions, or to attach but little importance to them, whilst others are actuated by motives of false economy, and in cases such as these, it is only by a fortunate chance that no bad effect issues. When persons are, however, made aware of their negligence it is often too late to prevent the disease and suffering which ensue. The writer has such an instance of neglect and its result before him, where a party occupied a house for some time. Towards the end of his term, he and his family suffered from illness eventuating in death, which was attributed to the condition of the house drains. An Inspector was sent to examine and report upon the state of these; but was refused admittance, and only some slight exterior reparation was done in connection therewith. His successor, being more enlightened in sanitary matters, before entering upon residence in this house caused a thorough examination of its sanitary condition to be made, when it was found that the drain, which passed beneath the floor, was without proper joints, the pipes being occasionally some inches apart, several barrow loads of black, rank sewage having accumulated beneath the floor.

The foregoing is too often typical of the worst form of ignorance and neglect of sanitation; but there are many other cases of a less glaring character which have been the cause of much disease, misery, and loss, emphasising the fact that the necessity for good sanitation is shared in and demanded by the whole community, the neglect of it, although it may be only an individual instance, endangering a wide area — either directly or indirectly—by its alarming and deadly results. A water supply contaminated through leaky drains, or imperfect condition of sanitary apparatus, may be distributed throughout a district with fatal effects, whilst the most dreaded and infectious diseases may be traced to bad drains, the germs of disease being contained in and conveyed by the escaping drain air. In many old houses, where the drainage has not been modernised, it is frequently the rule to find their condition unsanitary. Cases have come under the author's notice where the cesspool has, or cesspools have, been found beneath the kitchen floor, these having no proper ventilation. The yard of a house will perhaps be undermined with cesspools, the owners following the custom of emptying the contents of the old into a newly-dug one, these overflowing the one into the other, old wells being not infrequently utilised for such purposes. The cesspool and well are sometimes discovered side by side, the steining (when it exists) of the latter bearing distinct greasy marks of sewage percolation. The closets and other domestic arrangements are often placed under the staircase and other unsuitable corners, whence they ventilate into the house.

The position of storage cisterns in many houses permits no proper access for cleansing and inspection purposes, the cisterns themselves being without suitable covering, and not effectually cut off from communication with the drains. In some cases, where it is readily accessible from the bedrooms, servants may, if the cistern be not covered and locked, dip and wash filthy articles in the water. These are, then, some of the defects which frequently exist in old houses, and it is even far from rare in houses of recent date for such arrangements to be found, some being still perpetrated when opportunity offers.

Amongst the defects commonly met with of an undoubtedly injurious and dangerous character, may be enumerated leaky drains; drains with insufficient or varying falls, and with no provision for inspection and access for cleansing; defective and insufficient traps and gullies; the use of the filthy D trap, flimsy soil pipes, perhaps inside the house, and unventilated except through the joints; rain-water down pipes used as ventilators, perhaps unjointed and situated near windows, or terminating under eave of roof, and near storage water cisterns; waste pipes from sinks, with only a useless bell trap; openings of drains in floors for washing down purposes acting as ventilators; unsanitary closets; ventilation pipes taken into chimney flues, and other arrangements permitting the escape of poisonous effluvia.

Dr. Thorne Thorne, C.B., shows in his exhaustive report dealing with typhoid and diphtheria, that the typhoid fever death-rate has gone hand in hand with improvements in sanitation, it being about 0·38 per 1000 in the seventies, and has gradually fallen to 0·17, or less than half. Typical cases of fever outbreaks from imperfect sanitation are given by Dr. Chaumont, and Dr. Garrett, of Cheltenham, and others. The author has had several such cases of typhoid and diphtheria come under his notice, and upon investigation, nearly every case could be traced directly or indirectly to bad and defective sanitary arrangements; and it has invariably happened that upon prompt attention, and defects being remedied, the spread of disease has been checked, delay in such cases ensuring its further spread. One instance strongly suggests itself. A case of typhoid took place in a house, and a child, living in another part of the house, soon after contracted the disease. This the author investigated, discovering that the house was drained into a cesspool nearly filled up; the ventilation pipe—flimsy and defective—in connection with the cesspool being fixed against the house wall close to the window reveal of the room where the second case took place. The house was practically a new one, but in fixing the ventilation pipe in question one of the cast iron lugs projected in front of the window of this room, and this lug had been removed by a blow, taking with it a piece of the back of the flimsy pipe, making a large open fracture, partly obscured from sight, and on a level with the window of the room. It was by the smoke test that the fault was discovered, the smoke escaping in such quantities from this fracture as to blacken the brickwork reveal and window sash, and proving that the gas and impure air passing off from the cesspool in this manner escaped and found its way through the window into the interior.

Another case of a similar character was where two children died from diphtheria, which was traced to a communication between a filthy privy pit and the underneath of the floor of a house by a network of rat runs. The work of house drainage undertaken and carried out by many builders is too often considered by them as a secondary matter requiring little attention, and the fact that some of the principal parts when completed are hidden under ground and floors, or behind casings, gives opportunity for concealing much bad work. In order that houses should be healthy dwellings the drainage must be perfect, and where this work has been satisfactorily executed, it remains the duty of the occupiers to exercise cleanliness. To ensure that all drains should be above suspicion, good workmanship on the very best principles must be insisted upon, whilst those engaged on the work should be under the direction and control of competent and reliable authority.

If a town is sewered by a defective system, it is no reason or excuse that house drains connected therewith should not be of the best, for house drains in connection with bad sewers or cesspools have the greater need of perfection to keep back offensive effluvia and germs of disease—present in cesspools and defective sewers—from penetrating the dwellings, contaminating the air, and attacking the inmates. It is a mistake to think that because once house drains are made perfect they will remain so for an indefinite number of years. They should be periodically tested with a view of ascertaining whether any faults in their action or construction exist, such as fracture caused by frost, settlement, or undue pressure, or jar, trap bottom knocked through, or water-closet cistern out of order, and so giving insufficient flush to cleanse the drains. All of these accidents are possible, and although the fault may be small, its result may be serious unless rectified. Occupiers of houses should pay continual attention to the drains being kept clean and in order by proper flushing, and the occasional use of hot water with soda and disinfectants. Care should be taken to remove, by means of a proper bucket provided in connection with sink trap, any grease that may have been collected therein from the scullery sink waste, or by the use of a special flushing rim trap automatically removing the grease; and by further keeping the various gully traps under rain-water pipes, and in yards for surface water, &c., well cleansed and charged with water above the sealing line, more especially in hot and dry weather.

NOTES ON
PRACTICAL SANITARY SCIENCE.

By WILLIAM H. MAXWELL.

Assistant Engineer and Surveyor, Leyton Urban District Council, Author of "Drainage Work and Sanitary Fittings," "Ventilation, Heating, and Lighting," &c., Certificates of the Association of Municipal and County Engineers, and Sanitary Institute.

No. 43.

REFUSE DESTRUCTORS.

THERE is nothing new in the general principle of the treatment of refuse by cremation—it is a subject the sanitary importance of which has been recognised almost from time immemorial. Ancient history records that the purification of insanitary difficulties by fire was the mode practised by the Jews, Romans, and Greeks, and also by the natives of India. It is interesting also to notice that among the antiquities of ancient Rome is a pillar bearing the inscription—"Take your refuse further, or you'll be fined."[100] In Jewish history, too, we read that the valley of Gehenna or Topheth, where some of the Jews once sacrificed their children to Moloch, and which was subsequently regarded as a place of abomination, was made a receptacle for all the *refuse of the city* of Jerusalem, and that perpetual *fires* were kept burning in order to prevent pestilential nuisances.

As regards our modern English modes of disposal of refuse by fire, the practice and apparatus employed to-day are, like most other useful inventions, the result of much experiment and very many failures. It would, however, serve no useful purpose to give in detail,[101] even if it were possible, the particulars of all the various furnaces and machines which have from time to time been designed; but a brief summary of some of the more important attempts may be of interest as

[100] Lucian's "Ancient Rome in the Light of Recent Discoveries."

[101] For fuller particulars see paper on "Refuse Destructors," "Proceedings" Association Municipal and County Engineers, vol. xiii.

ndicating the course of the development of the cremation of refuse as we now know it.

Ordinary type furnaces, built mostly by dust contractors, were used in London and in the North some forty years ago, but they were unscientifically constructed and not adapted to the proper combustion of refuse. It was consequently found necessary to use coal or other fuel with the collected refuse to ensure its cremation. A furnace of this description was erected by the Corporation of Manchester about the year 1873.

An attempt was made in 1870 by Messrs. Mead and Co., dust contractors, at Paddington, to burn house refuse in closed furnaces. These were soon pulled down, as they failed to burn the refuse for want of draught, which defect was attributed to the furnaces being below the ground level. Mr. Codrington, however, observes [102] that, judging from a drawing, the great defect was want of sufficient area in the flue, which was only 1ft. 9in. square, for 110 square feet of fire grate.

About the year 1876, Mr. Fryer, Nottingham, erected one of his furnaces (which he styled the "Destructor" [103]) at Manchester, and others were added shortly afterwards. The towns of Birmingham, Leeds, and Bradford followed next in the erection of the "Destructor."

The furnace of Messrs. Pearce and Lupton, of Bradford, was invented about 1880, but after a fair trial in that town, conducted by the inventors, the experiment was abandoned.

Pickard (foreman at the Leeds Corporation Destructor Works) invented a refuse destructor which he called the "Gourmond." This furnace appears to have practically embodied the object of the more modern apparatus, the "cremator," in that it aimed at the purification of the gases given off from the cells by the action of fire.

Shortly afterwards Healey brought out his furnace, and a Fryer and Healey destructor was erected at Bradford. In this the purification of the gases was also attempted, but without the desired degree of success.

"Thwaites" apparatus consisted of a combination of a refuse furnace and boiler.

The furnace of Young, of Glasgow, consisted of an ordinary furnace with closed ashpits, into which air was blown by means of a powerful fan to assist combustion.

Mr. J. Wilkinson, of Birmingham, invented a furnace, and one of his type was erected at Blackpool. These furnaces are said to have cost a great deal for repairs.

Burton invented a long single furnace with two fires, the refuse being moved through by means of an endless chain.

The well-known "Bee-hive" was introduced by Stafford and Pearson, of Burnley. The accompanying diagram (Fig. 4) will suffice to illustrate the general arrangement of this destructor as erected in the parish yard at Richmond, Surrey, where two "bee-hives" were erected at a cost of £443 4s. 6d., including a chimney shaft 90ft. high, which were opened in 1884. These destructors were guaranteed to destroy 15 cwt. per hour for each hive, but they were constructionally weak, and the *wrought iron* furnace bars, which were destroyed with the heat in twenty-two weeks, had to be replaced by cast iron bars. The mode of charging the destructor was also faulty, and numerous contrivances in the shape of perforated dampers, baffle plates, &c., were inserted in the main flues with the object of intercepting the charred paper, dust, &c. There being considerable local opposition against the use of the furnaces, they were closed in June, 1885.

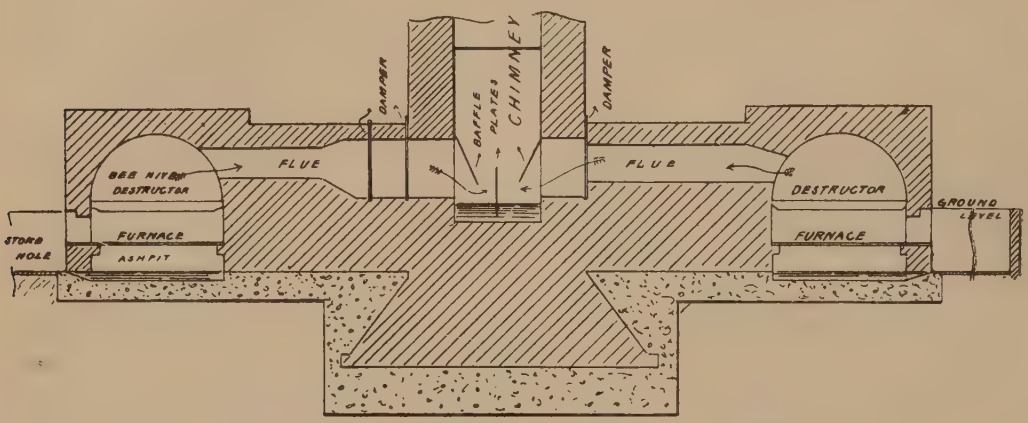

Fig. 4.—Section of the Richmond "Bee Hive" Refuse Furnace.

The "Bee-hive" was also erected at Bradford, where it was intended for the destruction of the market garbage and fish refuse, but as "the cost of wages and *fuel* amounted to over 4s. per ton of refuse destroyed, its use was discontinued." [104]

The "Nelson" destructor was patented in 1885 by Messrs. Richmond and Birtwistle, and an apparatus of this type was erected at Nelson-in-Marsden (Lancashire), but the construction of a larger destructor of an improved type has since been under consideration. Mr. T. Codrington, in his "Report on the Destruction of Town Refuse" (December, 1887), gives the following particulars as to the Nelson furnaces:—"There are three furnaces placed side by side consisting of horizontal fire grates 3ft. wide and 3ft. 6in. long, separated from each other by side walls, but com-

102 "Report on the Destruction of Town Refuse," by T. Codrington, M. Inst. C.E. (1887).

103 A somewhat inappropriate name, inasmuch as matter cannot be "destroyed," but simply changed in form.

104 "Proceedings" Association of Municipal and County Engineers, vol. xii., p. 106.

municating at the back with one drying hearth. For the purpose of experiment, apparently, the hearth is differently constructed opposite each furnace. Opposite the first it slopes from the back to the fire bars, and has apertures under iron shelf plates to admit heated air to the drying refuse. Opposite the second it is of fire-brick and level with the fire grate, and opposite the third it is sloping like the first, but of solid fire-brick. There are passages in the side walls of each furnace for the purpose of admitting air heated by passing through the walls to different parts of the furnaces. They open just above the fire-bars, and are intended to promote the combustion both of the refuse and of the vapours. The refuse is fed into openings at the back, and slides forward on the drying hearths to the fire grates, the products of combustion passing from the furnaces transversely over the refuse on the hearth, which constitutes, as it were, a part of the main flue. The middle hearth, which is level and forms a hollow between two inclined hearths, is intended for wet garbage, slaughter-house refuse, and excreta mixed with ashes. After leaving the furnaces the gases are passed over a coke fire on a fire-brick hearth, fed from above, and supplied with air through flues opening on a level with the hearth." In a trial in July, 1886, market refuse and garbage were burned at a cost of 2s. 9d. per ton for labour, and 1s. 9d. per ton for the coke furnace; the residuum, clinker and fine ash, were together over 50 per cent. of the refuse dealt with.

The apparatus invented by Hardie, of Burnley, consisted of an inclined furnace with a saddle boiler over, and it was proposed to dispense with chimneys by adopting the air-blowing principle.

(*To be continued.*)

It is a common thing to see children put money into their mouths. Seeing that babies make their acquaintance with the world by putting everything they can get hold of into their mouths, the danger may not be very great. There is some reason to believe that saliva has antiseptic properties. But one may readily conceive how diphtheria and other diseases, where the exchange from mouth to mouth has been made before the germs have been killed by drying, might easily be conveyed in this manner. It is a most disgusting and dirty practice, to say the least, and mothers should carefully teach their children never to put money in their mouths.

It is stated that numerous complaints have been made to London Vestries, particularly those in the western districts, as to the very dirty condition of the public thoroughfares; arising, it is alleged, from insufficient and defective scavenging, the sweepers in many cases being feeble old men employed in road sweeping as a means of relieving the poor rates. Mr. H. Lazarus will call the attention of the St. Pancras Vestry at its next meeting to the recent condition of Gower-street, Southampton-street, Upper Woburn-place, and other thoroughfares on the Bedford Estate. He will move that woodpaving be discarded in future, that the road sweepers be provided with working uniforms, and that sections of the roadways be entrusted to the care of individual sweepers held responsible for their condition.

PUBLIC GYMNASIA.

By Guy Cadogan Rothery.

It is a happy sign of the times that our leaders and rulers fully recognise the necessity of looking after the physical growth of rising generations. While, on the one hand, we have educationalists busily inculcating the "three R's," and on the other engineers and medical officers sweetening life by the promotion of practical sanitation, we also find a vigorous expansion of the "physical training" doctrine, and a widening of the basis of its application. Certainly physical training has never been held in too low an esteem at our great Public Schools, but the democratising of systematic physical education is only a comparatively recent movement in applied sociology.

In olden days sports on the village greens were common enough—racing, wrestling, and playing a rough game at ball kept young Hodge in good condition, counteracting certain bad tendencies engendered by too close an application to agricultural pursuits. The ancient games of Cornwall, Devon, and the Northern Counties may have been rather brutal, but they undoubtedly developed the bodies of young fellows, producing stout soldiers and sailors. But with the advent of a certain crabbed school of theologians village merriment was killed, the discontinuance of the village sports even awakening the alarm of that pedantic hypocrite James I., who penned a small volume pointing out the necessity of reviving the old games. Then came troublous times, followed by the purely artificial hilarity fostered by Charles the Profligate. After that we were busy again, and though village sports were revived, boxing and wrestling being specially encouraged, industrialism swooped down on us, and there seemed little time for play. Happily, however, the innate love of outdoor activity has never quite left us, and of late very real attempts have been made to systematise physical training and make it a living force among the people in town and country. Thus it is that we see physical training recognised as an important subject in primary schools for boys and girls. As regards gymnastics, we have certainly been largely indebted to our continental neighbours, for both in France and Germany the formal discipline to be obtained in gymnasiums has long been in favour with military and school authorities. Indeed, up to within a few years, the continental tendency was rather to over-exalt gymnastics. Unquestionably it is better to make pure gymnastics subsidiary to vigorous outdoor sports, as we find it in our own schools. But in crowded cities, where playgrounds are limited in extent and very different to green meadows or heath-covered commons, drilling and gymnastics are of greatest utility in the upbringing of children at the primary schools. Where drilling and simple exercises are practised little harm can be done even by the indiscreet, but where more important work is attempted greater care is requisite; and although teachers are grounded in elementary physiology and undergo a course of physical training, it seems advisable to go rather further in this direction. Of course in populous centres the school authorities can easily place the physical training, or, at all events, the supervision, in the hands of experts, male and female, but this is not always possible in smaller

schools, and then more should be expected of the head teacher.

Although gymnastic apparatus is useful, children and young people should only use it under competent supervision. This, unfortunately, is not always understood, and we occasionally find school gymnastic appliances accessible to children throughout playtime. This should not be, for accidents of a more or less serious nature may result, or bad habits be acquired. For the same reason we rather deprecate the policy adopted by some Local Authorities to erect somewhat elaborate gymnastic appliances, either in the open or in sheds in corners of public playgrounds. If these are not in charge of an attendant who knows something about the subject —rather an expensive matter—much harm may be done. Of course certain of the more simple appliances are quite suitable for school or public playgrounds, but these should always be carefully chosen with the advice of an expert, keeping well in mind that it is safer to be niggardly in this matter. Splendid work has been done for many years past in opening up parks and playgrounds for the public, where youngsters can romp and develope legs, arms, and lungs with some degree of safety to themselves and comfort to their elders. In connection with these open spaces giants' strides, well-constructed see-saws, and simple parallel bars can be safely allowed, but anything more elaborate must be looked upon with suspicion. The same arguments apply to schools. By all means let the school gymnasium be fitted up as lavishly as can be afforded, but keep it for serious work; only the most elementary appliances should be within the practically uncontrolled reach of the young people.

Various religious and social improvement societies have expended much energy and money in promoting physical training, and mainly through their agency many small towns and districts of large cities have been endowed with fine gymnasia, and by their means youthful workers find it possible to enjoy better health, owing to the exercise counteracting the bad effects of shop or factory life. Other classes of society, anxious to continue exercises began in school life, have called public gymnasia into existence. This tendency has also forced some Local Authorities to see what they can do to help the movement, and as a result we find many swimming baths emptied, planked over, and fitted up as gymnasia during the winter season. If such temporary establishments are under skilled management they serve a good purpose, and we hold that it is the duty of Local Authorities, as guardians of the welfare of the people, to see that only qualified individuals have charge of their transformed premises.

It is well to dwell upon the fact that gymnastics must be conducted on scientific principles, if good instead of harm is to be done. In competent hands such exercise is a means to health and general well-being; it is a genuine hygienic agent, not only capable of developing latent powers and keeping the body in a fit condition, but useful in controlling symmetrical growth and strength. Indeed, properly handled, it can become a curative agent, correcting malformations, giving the necessary fillip to weakened or partially atrophied parts of the system, arresting the descent towards chronic bad habits.

If we admit this — and we cannot do less than acknowledge its truth — it will be seen that it is of the utmost importance to health that the gymnastic appliances adopted for schools and elsewhere should be of the best manufacture and constructed on scientific lines, lines which admit of symmetrical training of individuals. It is not all training that is good, and certainly not all appliances that can be recommended. Some of the earlier apparatus used on the Continent rather encouraged foolhardy overtraining or straining, accounting for many of the breakdowns of persons who for a time stood high in the gymnastic world. In fact, gymnastics is a scientific branch of education, and as such, touching as it does on the health of the individual and community, it should be cultivated judiciously and under proper restrictions. Now-a-days all who are responsible for the management of large schools, orphanages, &c., pay considerable attention to the question, and as this tendency is, as we observed in the opening of the article, spreading vastly, it behoves all hygienists to study the subject in all its bearings.

IMPORTANT L.G.B. ORDER FOR LOCAL ELECTIONS.

THE parish meeting for the election of Parish Councillors in the present year will be held on Monday, the 14th of March, or on such other day not being earlier than Saturday, the 12th of March, or later than Wednesday, the 16th day of March, as may for special reasons be fixed by the County Council. The day of poll in the case of a contested election of Parish Councillors, and the day of election as regards the ordinary election of Rural District Councillors, Guardians, and Urban District Councillors in the present year will be Monday, the 4th of April, or such other day, not being earlier than Saturday, the 2nd of April, or later than Wednesday, the 6th of April, as in any particular case may for special reasons be fixed by the County Council. But it is necessary that in any parish in which polls for the election both of Parish Councillors and Rural District Councillors, or of Guardians and Urban District Councillors, as the case may be, have to be taken, the same day should be fixed for both polls.

Rule (1) of Part I. of the First Schedule to the Local Government Act, 1894, required that the annual assembly of the parish meeting should be held on the 25th of March in each year, or within seven days before or after that day. This rule rendered it very difficult so to arrange the dates for the proceedings at the annual election of Parish Councillors that one meeting should serve both for the election and for the annual assembly of the parish meeting. But by the Local Government Act, 1897, the rule above mentioned has been repealed, and it is provided that the annual assembly of the parish meeting shall in each year be held on some day between the 1st of March and the 1st of April, both inclusive. The difficulty in the way of one meeting being held both for the election of Parish Councillors and for the annual assembly of the parish meeting has thus been removed, and the dates in the New Parish Councillors Election Order have been so arranged as to admit of one meeting being held for the two purposes where this course is deemed desirable.

The Local Government Board, in making these announcements, adds the reminder that by the Ex-

piring Laws Continuance Act, 1897, the Local Government Elections Act, 1896, has been continued in force until the 31st December, 1898. Hence, if any difficulty arises in the present year with respect to any election of Parish or District Councillors or Guardians, or to the first meeting after any ordinary election of such Councillors or Guardians, or if from any election not being held, or being defective or otherwise, the Council or Board of Guardians has not been properly constituted, the County Council may, under Section 1 of the Act of 1896, by Order, make any appointment or do anything which appears to them necessary or expedient for the proper holding of any such election or meeting, and properly constituting the Council or Board of Guardians, and may, if it appears to them requisite, direct the holding of an election or meeting, and fix the dates for such election or meeting. Any such Order may modify the provisions of the Local Government Act, 1894, and the enactments applied by, or rules framed under, that Act, so far as may appear to the County Council necessary or expedient for carrying the Order into effect.

Section 1 (2) of the Act of 1896 expressly provides that a County Council may delegate their powers under the section to a committee, and the Local Government Board points out the importance of this power being exercised by the County Council. Cases came under the Board's notice last year in which advantage could not be taken of the powers conferred by the Act, because the difficulty to be met arose in the interval between the meetings of the particular County Council, and no committee had been empowered to deal with such matters.

The new Orders, of which the purport is explained in the above paragraphs, will now cease to be annual Orders, and have been so drawn up as to become permanent Orders, prescribing rules which shall, as far as practicable, apply to all elections.

A question having arisen last year in the Parish Council elections as to whether the demand for a poll could be withdrawn unless all the persons who made the demand joined in withdrawing it, express provision has been made in the new Rules on this subject. It will now be necessary, if the demand for a poll is withdrawn, that the withdrawal shall be made either by all the parochial electors who made it, or by such number of them that the number remaining is less than five or than one-third of those present when the demand was made, whichever number is least. If all the electors who made the demand for a poll withdraw it, the assent of the chairman to the withdrawal will in no case be necessary; but if some only of these electors withdraw the demand, and the number left is less than five or than one-third of those present when the demand was made, whichever number is least, the assent of the chairman to the withdrawal will be required.

GOOLE.—The Urban District Council has decided to send a deputation to consult Mr. De Rance, of Manchester, with a view to steps being taken to improve the present water supply or to obtain a new one. It has also decided to appoint a gas and water manager at a salary of £300 a year, instead of continuing the present dual control by sub-managers and a consulting engineer.

BIOLOGICAL SEWAGE FILTERS.

DR. REID has reported to the Staffordshire County Council on the experimental filters laid down at Tipton. Three experimental filters had been laid down by the District Council :—One of coke breeze, one of sand and gravel, and a third of sand and gravel aërated on Lowcock's principle of pumping air into the filter. The two former were completed in September, 1896, the last in January, 1897. In February, a coal filter was laid down by Mr. Garfield in substitution for the second. The three thus reported upon are the coke breeze, the Lowcock aërated, and the Garfield coal filters. At first the coke breeze filter—Dr. Reid gives no details as to its construction—was worked on Mr. Dibdin's charging and discharging principle, but later by a continuous flow of twelve hours followed a similar interval of rest like the other two. The Lowcock filter dealt with only half the proportion of sewage for the same area as the others. The purification per cent. estimated by removal of organic ammonia was 33·2 for the coke, 75·7 for the aërated, and 80·6 for the coal filter. Estimated from the diminished absorption of oxygen from permanganate solution, it was 29·0, 68·5, and 70·8 respectively. Considered from the point of view of oxidised nitrogen, the amounts were 0·38, 0·74, and 0·81 parts per 100,000 in the effluent against nil in the effluent as it reached the filter. A preliminary precipitation with the aid of alumino-ferric cake had apparently taken place in the effluent before it went to the filters. Perhaps this, with the non-inoculation of the filter and the constant stream together account for the coke breeze filter doing apparently so much less than at Barking and Sutton. At the latter it will be remembered that, without any preliminary treatment, the purification estimated by permanganate amounted to 86·5 per cent.

DRAINS AND TYPHOID.

CONTAMINATION of water supply, the eating of unwholesome shell-fish, and actual contagion, are the chief causes of typhoid. The remedy is so much in the control of Sanitary Authorities that the eradication of typhoid will be achieved *pari passu* with the advance of sanitation, and the appreciation of the fact that typhoid is a filth disease. Of course, drainage, with all its traps, sinks, pipes, &c., is a very complicated subject, but men and women must understand that smelling sinks, cesspools, and drains are poisonous to the inhabitants of the houses where they occur; and that not only are they the actual vehicles for conveying the germs of disease, but they cause a lowered vitality, and therefore a greater readiness to take disease. There is no doubt that there are a great many diseases caused entirely by imperfect drainage, and the increasing appreciation of this fact is doing much to dispel that doctrine which Charles Kingsley tried so hard to resist, and which Tennyson, in the poem of "The Village Wife," describes in a nutshell, thus :—

> "I thowt 'twear the will o' the Lord,
> But Miss Annie, she säaid it wus dräains."

PUBLIC HEALTH PROGRESS IN THE QUEEN'S REIGN (1837—1897).*

By T. RIDLEY BAILEY, M.D., of Bilston.

WE have recently celebrated the completion of sixty years of the reign of our Queen—a reign not only unprecedented in length in our history, but one the glories of which will be sung as long as England lasts. It is impossible to realise fully the marvellous changes that have taken place in the social, political, and commercial life of our country. Literature, art, and the drama have accomplished more than the most sanguine of their followers could have dreamt of; science has surpassed them in her achievements; and medicine—both curative and preventive—has a history not less worthy of being recorded. I must ask you to pardon my boldness in taking as my subject this afternoon, "The Progress in Public Health during her Majesty's Reign." Only a brief and partial sketch is possible within the limits of the occasion and of my own ability.

The state of sanitation and of sanitary knowledge throughout the country sixty years ago could hardly have been worse than it was. It is difficult for us to picture now the life and surroundings of the great mass of the people at that time, and only by reference to contemporary writings can we hope to know something of them. In the beginning of this century cholera, which had of course been known for hundreds of years in India, spread through Hindostan and ravaged nearly the whole of Asia. In 1831 it appeared in Europe, reaching England in October. In this country it continued for fourteen months, and on the Continent for six years. Among us it found conditions most favourable to its extension, and nothing can give us a better idea of the entire neglect of even the most elementary sanitary requirements than the description of the state of affairs revealed generally by the inquiries under the "Health of Towns" movement.

According to Rumsey, the arrangements for sewage and drainage of towns, and for cleansing the surface of streets, were most defective. Sewers were comparatively rare; such as existed were constructed on wrong principles, and cesspools were common. House drains were usually wanting, and, when present, had no connection with the sewers. The result was that the subsoil of towns was generally studded with sinks and cesspools; the surface of courts, alleys, &c., was covered with middens and refuse heaps, and the atmosphere laden with impurity and noxious gases. The drainage of land was rare, and stagnant water and filth common. The supply of water was deficient in quantity, inferior in quality, and most defective in the methods of its distribution to dwellings. Open ditches and foul water-courses laden with impurities existed in the towns and outskirts; offensive occupations and deposits were to be found on all sides; factories and workshops, which were erected anyhow and anywhere, were much overcrowded, while ventilation was conspicuous by its absence.

The houses of the poor were usually damp, closely packed in narrow streets and courts, built without regard to style or convenience, the sleeping-rooms small and overcrowded, entailing moral and physical degradation. Such structures invited and developed attacks of epidemic disease. The existing laws were quite inadequate for protection against local nuisances and for the promotion of necessary reforms. No proper authorities were in existence to administer the elementary enactments then in force, to promote a sounder view of public needs and personal habits, or to create and stimulate a desire for a better and a healthier environment. The local jurisdictions actually in force were inefficient, interfering with, and trespassing upon, each other's functions, and hopelessly preventing the proper execution of sanitary measures. Medical Officers of Health and Sanitary Inspectors were not even thought of. No central authority had been formed to exercise any control over Local and subordinate Authorities. Pauperism abounded, no less than 12 or 13 per cent. of the population in 1834 receiving relief from the Poor Rates. It is stated that "before the Poor Law Act of 1834 was passed, throughout four-fifths of England the majority of the inhabitants which had not the advantage of charitable infirmaries or dispensaries were attended under the Parish Medical Contract."

Only in the year of the Queen's accession was the Act for the Civil Registration of Deaths, Births, and Marriages, passed—an Act that was a necessary preliminary to the proper study of the etiology of disease, for the classification of the various causes of death in different localities, and for the determination of the influence of sex, age, and conditions of life on the public health—an Act which it is needless to say has been of the greatest possible service in the development of preventive medicine. Before that time, though the country had been frequently overrun with every kind of pestilence—typhus fever, small-pox, cholera, scarlet fever, and the like—no registration of the causes of death had been instituted. Indeed, it was largely, owing to the frightful mortality of the cholera in 1831—when 50,000 lives were known to have been sacrificed, though probably that figure was exceeded by many thousands—that a basis of future inquiry was provided by a careful collection of statistics. We see the result in the series of brilliant achievements in the prevention of disease that are among the greatest glories of this reign.

After this, a comparison could be made, *inter alia*, between the death-rate in different parts of the country, and on a "further examination of the difference in the general death-rates of towns and country districts, it was found that whereas the annual mortality per cent. of population was 1·8 in country districts, it was as high as 2·6 in town districts. In 1841 the Registrar-General pointed out that, whereas the mean duration of life in Surrey was forty-five years, it was not more than thirty-seven in the metropolis, and only twenty-six in Liverpool. Pulmonary consumption was also now ascertained to be one of the diseases which exhibited a striking excess in the case of town life. In fact, the general mortality was found to be increased 44 per cent. by the then condition of English towns and cities, and much that led to this excess of death was rightly held to be capable of remedy."

CHOLERA.

The history of cholera is most intimately associated with the record of sanitary medicine in this country. On four occasions this disease has in-

* Presidential address to the members of the Midland Branch of the Incorporated Society of Medical Officers of Health, October 7th, 1897.

vaded our shores, causing an enormous number of deaths, and leaving misery and despair on every side. The first visitation was in 1831—2, and though this does not, strictly speaking, come within the scope of my subject, the town in which I now reside suffered to such a frightful extent that a few remarks may be of interest and serve to show the sanitary conditions at the commencement of the period under review. In Bilston, with a population at that time of 14,492, there were in seven weeks no less than 3568 cases and 742 deaths, including two medical men. "The sanitary condition of the town," to quote the words of a local writer, "was deplorable. Foulness and filth were seen in the old-fashioned streets, in the low courts, and everywhere. Stagnant pools sent up their deadly vapours, sink holes their effluvia, and wretched hovels their thrice-breathed atmosphere. Undoubtedly the chief cause of this state of things arose from the character of the people, who, brought together in great numbers by the demand for labour in the vast mines and forges of the town, were composed of the worst characters, morally and socially, that could possibly be conceived—similar to the hordes of animated life that stream into some newly-found gold region. Being of degraded habits, and the houses numerically inadequate for the people's accommodation, they herded together like swine, the filth of their tenements and their persons thus giving strength to the venom of the avenger." It is added that "the cost of the funerals of the victims would have permanently drained, sewered, and watered every house that was visited; that policy and pity cried aloud for street and tenement reform, and demanded the opening of those large 'brick graves' called courts, alleys, and back squares, where the poor are buried alive, amid the gloom, damp, corruption, human scoria, and every other attributes of the churchyard, except its sanctity and peace." This epidemic was also extremely fatal in many parts of the country; Glasgow, for instance, showing a mortality of 2842, or 140 per 10,000 of the population.

It was natural that the pestilence passing over the whole land should stimulate observers to discover, if possible, its cause or causes. It was observed that in England, at least, isolated outbreaks occurred in the autumn of the first year, that the disease died out in winter and reappeared with great virulence in the spring or early summer. From this it was concluded that high temperature favoured, while cold retarded, the appearance of the disease. Further, it was known that it was always imported by persons coming direct from infected places, local outbreaks occurring in the seaport towns where they landed, and that it subsequently followed the line of traffic, showing that human intercourse was largely concerned in its propagation. This disease appeared for the second time in England in September, 1848. From that date until the end of March, 1849, only 988 deaths were registered, but in the summer following there was a rapid increase. During the year 1849 there were in all 53,000 deaths from cholera, besides nearly 20,000 from diarrhœa. The result was that there were no less than three official inquiries instituted. The report issued by the Board of Sanitary Works contained an interesting account of the progress of the epidemic from the East, and showed that the disease generally followed, as we have said, great lines of human communication by land and sea.

The second inquiry resulted in Dr. Farr's report to the Registrar-General—one of our English medical classics. In this brilliant paper, by the use of historical and typographical illustrations, the importance of the sites of towns and the effect of various degrees of elevation on the health of communities is clearly demonstrated. The statistics of cholera in London supported Dr. Farr's hypothesis that the number of deaths varied inversely according to the altitude of the localities.

The third inquiry, by the College of Physicians, derives its value chiefly from the researches of Dr. Baly. Among other things, Dr. Baly insisted on the relation of the disease to density of population. "He found that in the 134 more thickly-inhabited registration districts of England where the higher rate of mortality occurred, the population being 915 to the square mile, the deaths averaged 65 to 10,000 living. In the 404 districts of lower cholera mortality, there were on the whole 235 inhabitants to the square mile, and the deaths averaged only 7 in the 10,000, while there were no deaths from cholera in the remaining 85 districts, where only 122 persons on the average resided on a square mile."

In the August of 1853 cholera again showed itself in London and the North, and in the following year England had its third great visitation, the disease having come directly from the German Baltic ports. By the end of the year over 20,000 deaths in England and Wales were registered, in addition to a very large mortality from diarrhœa.

To Dr. Snow belongs the credit of first making the discovery that the cholera poison was contained in the evacuations, that the disease was propagated by the entrance of small quantities of such evacuations, mostly through contaminated water, into the alimentary canal. At the period referred to, all the sewers of London were discharged into the river Thames, from which the water for drinking purposes was taken by two companies—the Southwark and the Lambeth—and naturally cholera prevailed extensively among their customers. Between 1849 and 1854, however, one company—the Lambeth Company—had removed its intake further up the river, thus improving considerably the quality of its water. The result was most significant and instructive. Not only did the disease pick out, as it were, the various streets supplied by the Southwark Company, but Dr. Snow was enabled, after careful examination, to emphasise the difference by the following figures :—

	Population in 1851.	Cholera deaths in 14 weeks	Cholera deaths per 10,000
Houses supplied by Southwark Co.	266,516	4093	153
Houses supplied by Lambeth Co.	173,748	461	26

The well-known outbreak in connection with the pump in Broad-street, Golden-square, need only be mentioned. "There had been a few cases," says Bristowe, in his "Theory and Practice of Medicine," "in the neighbourhood during the month of August, which, up to the 30th, had resulted in 9 deaths. On the 30th, at least 8 cases, which ultimately proved fatal, occurred; on the 31st, 56; on September 1st, 143; on the 2nd, 116; on the 3rd, 54; and then daily until the 9th, 46, 36, 20, 28, 12, 11; after which the disease rapidly disappeared. No less than 616 persons were ascertained to have been attacked fatally with cholera within this area, between August 19th and September 30th, of whom at least 415 contracted the disease between August

31st and September 4th, inclusive." At this very time, too, the disease did not affect several groups of people living in the same district who had their water from a different supply, and there can be not "the shadow of a doubt that this sudden and evanescent outbreak was distinctly due to the use of the sewage-contaminated water of the Broad-street pump, occupying the centre of the affected area, the water of which was held in great repute, and was largely drunk by those who lived in its neighbourhood."

These and similar investigations clearly showed the cause of cholera in a large number of instances, but it was reserved for Thiersch, Sanderson, and others to show by experiments that the poison of cholera—which we now know to be a bacillus—is contained in the alvine discharges and infest the mucous membrane of the bowels.

"It was ascertained that when, under certain conditions, mice were fed with cholera evacuations, they were attacked with symptoms that proved rapidly fatal, and that both symptoms and *post-mortem* appearance had a very close resemblance to those which indicate human cholera. The chief points of likeness consisted in the rapidity and intensity of the disease; in a remarkable lowering of the temperature; in the accumulation in the intestines of thin fluid containing bacteria, other lowly organisms, and abundance of shed epithelia, and in the discharge of loose stools from the anus. The method adopted by Dr. Sanderson to infect the mice was to soak pieces of filter paper in fresh cholera evacuations, or in the contents of the bowels of patients who had died of cholera, to dry them, to ascertain by weighing the quantity of solid matter thus added to them, to cut them into pieces one inch square, to soak them in bacon fat, and then to administer them to the mice. The mice under these circumstances ate them greedily. The consequences were—that of mice fed with paper prepared from evacuations which had not been allowed to stand more than twenty-four hours, that is on the first day after passing, 11 per cent. were affected; that of those fed with paper prepared on the second day, 36 per cent.; that of those fed with paper prepared on the third day, every one; that of those fed with paper prepared on the fourth day, 71 per cent.; and that of those fed with paper prepared on the fifth day, 40 per cent. Paper prepared subsequently had no effect. These experiments show that the cholera evacuations have little or no intensity of action when perfectly fresh; that their virulence increases up to the third day, diminishing during the fourth and fifth days, and that they lose all specific properties after that date. The evacuations from the diseased mice produced the same effects on healthy mice as did true cholera evacuations; and further, all experiments made by Dr. Sanderson in the month of November failed absolutely, probably, as he suggests, on account of the low temperature then prevailing."

In 1866—the year of the fourth cholera epidemic—the water contamination theory received strong confirmation in the East of London, where the localisation of the epidemic was almost entirely due to the distribution to these districts of impure and unfiltered water by the East London Water Company. At the same time, further research, both at home and abroad, clearly showed that the laws influencing the incidence of cholera were very similar to those influencing typhoid fever, and that, in the words of Simon, "excrement sodden earth, excrement reeking air, excrement tainted water, are for us the causes of cholera." This epidemic was much less fatal than the previous ones, as a result, no doubt, of the partial removal of those conditions of filth which were known to be the essentials in the spread of cholera.

The mortality of the disease in the three epidemics is given by Sir R. Thorne-Thorne as follows:—

Cholera Mortality.

	England and Wales.		London.	
	Total deaths.	Deaths per 10,000 living.	Total deaths.	Deaths per 10,000 living.
1849 ..	53,293	30	13,565	51
1854 ..	20,097	11	10,684	43
1866 ..	14,378	7	5,548	18

As a result of the experience and discoveries of the last sixty years we have now no fear of cholera. If it should appear again on our shores—as indeed it has done more than once since 1866—our knowledge of its causes and the conditions of its propagation will enable us to prevent it spreading widely in the country.

In concluding this part of my theme, I will quote the words of Sir R. Thorne Thorne in condemnation of the antiquated system of dealing with the disease by quarantine, which to the credit and advantage of this country has now been abandoned: "The system of quarantine has again and again shown itself to be impotent for good, and being so, its vexatious and inhuman characteristics stand out the more prominently. Above all, it has a blighting effect on sanitary progress. So long as Governments tell their peoples that a line shall be drawn around them across which disease shall not pass, so long will those peoples be reluctant to spend their money on the promotion of true measures of prevention. The quarantining countries are essentially those which cholera invades. Taken as a group they are those where true sanitary progress is at the lowest ebb, and with the experience we have before us, I would in conclusion ask, much in the words I used at the Rome Conference, Is it likely that this nation will sacrifice her well-tried system of prevention for a restriction of five days' quarantine?"

(To be continued.)

THE PLUMBERS' COMPANY.

At the quarterly meeting of the Worshipful Company of Plumbers on December 29th, the Registration Committee was received by the Master and Wardens at the Guildhall, and were afterwards entertained at dinner, under the presidency of Alderman Richard Hind. Professor Garnett, Dr. Vacher, and the representatives of the National Association of Master Plumbers and the United Operative Plumbers' Association of Great Britain and Ireland, were among those present.

Mr. Bishop, past Master of the Company, spoke of registration as distinguishing a skilled calling from a trade one. Mr. W. Titmas referred to the old race of plumbers being better trained in workmanship than many in the present day. Mr. George Taylor expressed the opinion that the leading workmen of the period are equal to their predecessors in point of manual skill and superior in

technical knowledge. He urged the development of more practical instruction among the younger members of the craft. The Master of the Company spoke of apprenticeship being essential to the training of the plumber competent to execute sanitary work with safety to the public. Professor Garnett said the Plumbers were foremost among those connected with the building trades in recognising the value of technical instruction, and he pointed out that the Technical Education Board had encouraged the establishment of classes for plumbers in London. Dr. Vacher instanced the Liverpool Corporation as one among the larger municipal bodies which were alive to the importance of the plumbers' registration system as a branch of public health work.

ALLEGED INSANITARY PROPERTY.

AN important discussion *re* the legality of a sanitary order took place before Mr. D'Eyncourt, at North London Police-court, on Tuesday. The summons was taken out against Mr. Harold Morris (one of the City Commissioners of Sewers) in respect of the drainage of a house owned by him at Wyatt-road, Highbury.

Mr. Bramall appeared for the Islington Vestry; Mr. Bodkin was counsel for the defence; and Mr. Banister Fletcher had been subpœnaed for the defence.

The case was before Mr. Bros at this Court in November last, when the order was made that all sanitary defects should be remedied, but without specifying the particular work.

Mr. Bramall was proceeding to show wherein the magistrate's order had not been complied with, when Mr. Bodkin took objection to the summons on the ground that the Vestry had failed to comply with Subsection 5 of Section 5 of the Public Health Act, which said that if the person upon whom the order is made so requires the Public Authority shall specify exactly the work required to be done. Mr. Morris had applied on several occasions, and was now in the position of a man asking, "What will you have me to do?" Mr. Bramall replied that there was no doubt as to the defective drainage, and the only question was as to whether there should be the smoke or the water test. Mr. Bros had made the order upon the defendant to do what was necessary; and it would be a bad precedent for Mr. D'Eyncourt to re-open the case.

Mr. D'Eyncourt said he did not intend to do so. The best way would have been for the defendant to have mandamused Mr. Bros to further hear the case. He (the speaker) held that the order on the face of it was a perfectly good one, but he would grant an adjournment so that each side might interview Mr. Bros on the matter.

The adjournment was accepted.

TO OUR READERS.

The Editor solicits the co-operation of readers in making THE SANITARY RECORD *more attractiv by means of pen-and-ink sketches, photographs, and diagrams. There are many phases of sanitary work which lend themselves admirably to illustration. By this means not only individual articles, but the journal as a whole will be heightened.*

Sanitary Inspectors' Associations.

LONDON.

THE usual meeting of the Sanitary Inspectors' Association was held on Saturday, at the Carpenters' Hall, London-wall, E.C., under the chairmanship of Sir John Hutton, J.P., L.C.C., the President of the Association; supported by Mr. T. G. Dee, the Chairman of the Council; Mr. C. W. Raymond, the hon. treasurer; Messrs. W. W. West, I. Young, Ashdown, Legg, Henley, Bridell, Jordan, Barth, Alexander, Fairchild, Duck Shawcross, Moss Flower, and Mr. E. Tidman, the hon. secretary. After formal business,

The PRESIDENT, who was received with loud applause, gave the customary new year address. He said it was the universal desire of the Association to perpetuate the memory of the past presidents, and so it was proposed to form a fund, from which members could be encouraged in their studies and researches, in the interest of the public health. A liberal and practical proposal had been made by some of the members to found a Chadwick and Richardson Memorial Fund. An offer of a contribution of 50 guineas had been made provided that within nine months the fund be raised to 500 guineas. He thought the Association should not have any difficulty in carrying this out, if each member would help. Competitions for the prizes were to be held yearly, in such form as might be deemed best, either by having special contributions, or for the best papers read at the London or any branch meetings. Having referred to the successful visit of over one hundred members of the Association to Belgium, the President proceeded to remark that the salutation of the Association to all men is "Health and Long Life." Recently, the civilised world had been amused at the ornate style adopted in addressing a certain Emperor, but the Eastern salutation, "O King, live for ever," could be readily understood and appreciated when it was remembered that life is a symbol of power and creative force. To promote longevity was an aim and result of the work of the Sanitary Inspector. In 1660, the rate of mortality in London was 80 per 1000 per annum, but the death-rate in the county of London in 1896 was only 18·9. Many contributory causes had operated in producing that result, not the least of which in recent years was the zealous labour of the Sanitary Inspector. These figures were more remarkable considered in conjunction with the increased number of houses in London. In the year 1801, there were 142,042 houses in London; in 1831, they had increased to 246,839; while in 1896, they amounted to no fewer than 596,030. Then there was also an increase in the density of population; in 1801, only 958,788 persons lived in London; while in 1896, the population amounted to 4,443,018. The Sanitary Inspector specially dealt with certain forms of what may be designated preventable diseases—those over which, humanly speaking, man has control. No epidemic could resist clean houses, clean air, clean water—in a word, cleanliness. Many authorities could be cited to show that the present death-rate of 18·9, light as it is, could be still further reduced. No one could be familiar with the poorer districts of London without feeling convinced that this is so. Therefore, the

time had not arrived for the relaxation of any effort, but without an optimism which might lead to false security, they might feel gratified with figures that show how encouraging a result might be obtained under unfavourable circumstances. He believed that many Local Authorities would find an actual economy in increasing their staff of Sanitary Inspectors. There was a very laudable rivalry among some Local Authorities to keep their districts in the best possible sanitary order, but in others a falsely-called "economy" prevented the engagement of a sufficient staff of Inspectors, or, indeed, the payment of those already engaged on a sufficiently liberal basis. They were, in fact, just living down the old notion that a man who had failed in every other walk in life was the man to be appointed a Sanitary Inspector. Now the members of the Association were anxious to secure by competitive examination the very best men to fill any vacancies, and there was no fairer or more popular way of selecting those who presented themselves for the public service, and the following had been suggested as the constitution of an examining Board: Three members to be nominated by the Local Government Board, two by the Sanitary Institute, and one each by the following bodies: the Society of Medical Officers of Health, the British Institute of Public Health, the Worshipful Company of Plumbers, the Worshipful Company of Carpenters (to whom the Association was so much indebted for the use of their hall), the Royal Institute of British Architects, the Association of Municipal and County Engineers, and the National Health Society. He hoped that this useful work would be accomplished before long, for anything tending to improve the status of the Sanitary Inspector would be greatly to the advantage, not only of themselves, but also to the general public. At present the Association consisted of 592 ordinary members, 52 honorary members, and 26 associates, actuated by one common desire and object. In their ranks would be found men of distinction, together with members of the Institute of Civil Engineers, Sanitary Institute, Incorporated Association of Muncipal and County Engineers, Surveyors' Institute, and Society of Architects. Theirs was not a London Association, but one which extended over the United Kingdom, and as their friend he warned them that there was no surer way to reduce their power and authority than by any attempt to cut up this compact body into independent associations. As an illustration of the reasonableness of their claims in regard to superannuation, a paragraph in the memorandum of their Bill could be aptly quoted: "Sanitary Inspectors are engaged in the performance of duties which almost daily endanger their health and lives, viz., investigation of the causes of and the abatement of dangerous nuisances, investigation into the causes of infectious disease, and the taking of the necessary measures to obtain and carry out isolation and disinfection." Upon the fearless discharging of these duties by Sanitary Inspectors depended to a large and increasing extent the health of the community, and the late Parliamentary Secretary of the Local Government Board, stated that "the mortality among Sanitary Inspectors is greater than among soldiers in wartime." In equity, therefore, they were entitled to special and commensurate protection and provision for themselves and those dependent upon them should they become victims in the execution and conscientious discharge of their duties. The provision for a contribution from salaries made in the Bill was in accordance with the spirit of the age; and, further, it was the method adopted by the London County Council in its recent Superannuation Act, which in practice worked perfectly. An amendment of the terms of the tenure of the Sanitary Inspector's office was also of great importance. The present position, he said, is that whilst the Public Health (London) Act, 1891, had secured a permanent tenure of office in the case of Medical Officers of Health, Sanitary Inspectors had to accept appointments on such conditions as the Local Authorities think fit. The result was that Inspectors were dependent on the goodwill of individual members of the bodies appointing them, and the consequence naturally followed that Inspectors were liable to be influenced in the discharge of their duties from fear of offending those on whom they were dependent, and might thus be deterred from calling attention to defects to remedy which would involve expenditure by members of Local Authorities, who are the owners of property subject to inspection by the officer whom they appointed, and the renewal of whose appointment is in their hands. Foulness was the source of disease, and cleanliness is its preventive. Although science had come to their aid in many ways, cleanliness was an immense factor in all practical sanitary work. The question of the purity of the water supply to London would, he hoped, receive the early attention of thoughtful people. He would not refer to committees and commissions which had resulted in dangerous delays and increased complications, but he should not be surprised to find that London in a few years might have mournful cause to regret her suicidal neglect of securing a new source of supply. A tidal river could not, under the most favourable circumstances, be an ideal source of water supply for so large a section of the vast community of this city. Such an epidemic as that which afflicted Maidstone—where, strangely enough, the total number of cases stood at 1897, the number of the year just closed—might at any time attack London with consequences too alarming to contemplate, and he was convinced that Londoners should protest strongly against this happy-go-lucky policy in dealing with water supply. In concluding, Sir John said, "Your successes in the large field of sanitary work are not to be gauged by the number of convictions obtained through your instrumentality, for prevention is better than cure. You are the ministers of health to all classes, and especially to the teeming population of workers in this great city, a sacred trust, and amid the many discouragements you may meet with, let the priceless possession of a clear conscience add further to your zeal, to your praise, and to your country's good." (Loud applause.)

Mr. T. G. DEE (Westminster) proposed a hearty vote of thanks to Sir John Hutton for his address; this was seconded by Mr. W. W. WEST (Walthamstow), and supported by Messrs. LEGG (Hackney), Mr. T. C. MOSS FLOWER, C.E., Mr. SHAWCROSS (Lancs), and Mr. W. H. GRIGG (Fulham), Mr. DUCK (Plumstead), and Mr. H. ALEXANDER (Shoreditch), and carried with acclamation. Several of the speakers referred to the President's remarks upon the proposed constitution of Examination Board, and urged that the policy of the Association had always been that upon any such body the

Association, as comprising practical Sanitary Inspectors, should be represented on it.

Sir JOHN HUTTON, in replying, concurred in this view, and expressed the conviction that any Board nominated by Government should be one on which the Association was largely represented. He referred to the noble work done by the two past Presidents, and as a mark of his gratitude and appreciation of their labours, announced that towards their memorial fund he would be pleased to be allowed to contribute fifty guineas. (Applause.)

The usual private conference of members was then held, and the proceedings terminated.

DIPHTHERIA AT PUTTENHAM.

AT the last meeting of the Guildford Rural District Council, the Medical Officer reported that sore throat had for several weeks been very prevalent at Puttenham, culminating in two houses being invaded during the past month with a very virulent type of diphtheria. Three children were attacked in one house, and two in another. They were all removed to the hospital, and the three former succumbed from toxine poisoning and cardiac paralysis. The Medical Officer reported that it was only fair to state that two of the patients were in a hopeless condition on admission, whilst the third soon developed symptoms of blood poisoning. The Rector had closed the schools. Three cases of erysipelas had been notified from Merrow, Worplesdon, and Shere respectively. Sore throat and attacks of diphtheria had not been uncommon at Puttenham—especially the former—during the last three or four years, to say nothing of the geographical position of the village, lying low in a hollow beneath the Hog's Back, and so protected from the purifying effects of wind currents, the village itself is one long urban street. The gardens are small, and in some cases there are none at all, and in the absence of any attempt at scavenging the ground in close proximity to the residences has, it appears to me, become saturated with sewage, and this naturally predisposes to sore throat and other sickness. Some of the water supplies have proved very impure, probably owing to sewage pollution. Several of the principal inhabitants had consulted him and the Surveyor as to a solution of the difficulty, and he had informed them that, in his opinion, nothing would tend to improve the healthiness of the village so much as a good scavenging scheme or a sewer right through the village. The former would not be a heavy tax on the parish; on the other hand, given a suitable outfall, the gradients of the village street were well adapted for a small sewer. A committee was appointed to consider the matter, and report to the Board.

LONDON, E.C.—Clerkenwell has been smitten with a serious epidemic of measles, which has been traced to the Sir Hugh Myddelton Board School, in connection with which no less than seventy cases have been reported. All that can be done is that which was recommended by the Vestry of Clerkenwell to the School Board—to extend the Christmas holidays at this particular school by a couple of weeks, in order that the disease may be stamped out.

Reviews.

Humanitarian Essays: Being Volume III. of Cruelties of Civilisation. By MAURICE ADAMS and others. Edited by HENRY S. SALT. Price 1s. William Reeves, 185, Fleet-street, London, E.C.

THIS is one of the Humanitarian League's publications, and contains seven essays. Mr. Maurice Adams, on the "Sweating System," shows how six Inspectors, four juniors, aided by ten assistants, are supposed to look after over 10,000 factories, and upwards of 18,000 workshops in London and neighbourhood, and quotes Victor Hugo:—"In England they venerate so many laws that they never repeal any. They save themselves from the consequences of their veneration by never putting any of them into execution." For the full solution of the problem, Mr. Adams looks forward to the growth of sympathy, guided by reason, which shall intelligently organise the whole of life in accordance with insight and love.

In the "Gallows and the Lash," Mrs. Bonner advocates indeterminate sentences for first offenders, which would probably include half the murderers; the abolition of the capital punishment, and the imprisonment for a term in the discretion of the judge. We agree with the authoress that the death penalty does not deter either in England or abroad; but we are not prepared to support the abolition of flogging, which might be more frequently carried out in cases of unprovoked personal assault.

In the "Shadow of the Sword," Mr. G. W. Foote points out that of every pound of taxes 16s. 1½d. goes for war, war debt, or preparation for war. We are not of the same mind with our author, that "war is the game of sovereigns and statesmen," but rather that "war is just in self-defence, or in defence of a neighbour unjustly attacked."

Probably the remedy may be found in Europe, at least by a Union of States:—

> "Till the war drums throb no longer, and the battle flags are furled,
> In the Parliament of man, the Federation of the World."

Mr. H. Roberts, in "Public Control of Hospitals," desires that the hospitals should be taken over by the County Councils, who should elect a board consisting of a majority of their own members, and a minority of surgeons and physicians elected by the hospital staff. The hospitals to be thrown open to all who cared to use them, provided they were ill enough, regardless of class or character—a form of State Socialism likely to stop the perennial flow of charity.

Mr. J. Collinson, in "What it Costs to be Vaccinated," shows by statistics the evil effects of the system, and points out, no doubt to his own satisfaction, how the disease can be eliminated by careful sanitation, without running the risk of inoculating the patient with some other disease.

"The Humanities of Diet," by H. S. Salt, is an earnest appeal advocating from the vegetarian point of view the humane protection of the lower animals.

The series concludes with an appeal to teachers to discourage cruelty and cruel sports, and to preach and practise kindness to animals.

Children under the Poor Law: their Education, Training, and After-care, together with a Criticism of the Report of the Departmental Committee on Metropolitan Poor Law Schools. By W. CHANCE, M.A., Trinity College, Cambridge, Barrister-at-Law, Hon. Sec. Central Poor Law Conferences. Author of "The Better Administration of the Poor Law." Price 7s. 6d. Swan, Sonnenschein, and Co., Ltd.

THE author of this book, in dealing with a subject which to most people is of the "dry-as-dust" order, has succeeded in producing a volume crammed with valuable and interesting information and teeming with references and authorities.

Mr. Chance describes at length the various methods of dealing with children in workhouse, district and separate schools, cottage homes, and isolated homes, the use made of public elementary schools and the boarding-out system. The two main disadvantages of workhouse schools are first the difficulty of securing and retaining good teachers, and the second the monotonous life led by the children; there is also the evil of close contact with adult paupers. In the district and separate schools the children are separated from adult paupers, they have permanent teachers, and the future of the children is assured; on the other hand, they lead barrack-like lives, and there is the loss of the family tie. With the cottage homes there is a certain kind of family life, and the health results are better. In the isolated homes the institutional life is abolished, and the children are more in contact with every-day life; it is the nearest approach to family life, and the education received at the neighbouring Board Schools is far superior to the ordinary workhouse schools. The defect in the boarding-out system appears to be that so many cases of cruelty to, and neglect of, children go undetected; therefore, to be successful, a most stringent supervision must be exercised by the boarding-out committees.

We have it on the authority of Miss Mason, a special Inspector for boarded-out children, that the immortal Oliver Twist was brought up in an isolated home, and was not, as many suppose, a workhouse child. The school to which he was relegated was under the parental superintendence of an elderly female, who professed much affection for the "dear children," and whom Mr. Bumble called a humane woman. Boarding-out and small homes are no new things; what is new is the system of safeguards which now surround them, and without which, unless carefully applied, they will revert to the conditions described by Dickens.

Some of our readers may be unaware of the fact that Boards of Guardians have nothing to do with the education of those children who are classed as out-door paupers. On January 1st, 1896, 54,052 children were receiving indoor, and 184,437 out-door relief. Of the 54,052 children, only 24,475 were being educated in Poor Law schools, the great majority attending the public elementary schools.

Mr. Chance does not advocate any particular system. One system, he says, "suits one locality better than another, while a combination of systems is also useful." To anyone who is interested in the manner of the up-bringing of the units who go to make up the future men and women of the Empire, to those who are deep in the work of Boards of Guardians, and to all those who desire only to glean something of the good work being done under the Poor Law for our children, we commend Mr. Chance's work as being readable and up to date. It is satisfactory to learn that the children from the Poor Law schools seldom come back to the workhouse at any time during their lives. The children have, in fact, been depauperised, and many of them have mounted high in the social scale. To quote but a few instances: One boy is now the head master of a large Board School in Bristol, another is sub-librarian at the Birmingham School of Art, and another is a scout at All Souls' College, Oxford.

General News.

BOGNOR.—A sum of £150 is to be expended for the erection of public conveniences. A further sum of £230 is proposed for similar purposes.

FINEDON.—A committee of the Urban District Council is making arrangements for the acquisition of the land necessary for a proposed water supply.

ARDSLEY.—The Urban District Council is applying for sanction to borrow an amount necessary for the purchase of a road-roller and scarifier.

BROADSTAIRS AND ST. PETERS.—The Local Government Board's sanction has been received to the proposed borrowing of £1060 for the provision of public conveniences.

LOWESTOFT.—The Town Council has resolved to apply to the Local Government Board for sanction to a loan of £10,000 for conversion of the privies existing in the borough into water-closets.

PADDINGTON.—The Vestry has agreed to rescind the resolution authorising a public lavatory to be constructed in Pickering-place for females as well as males, and to substitute in lieu thereof a resolution providing for the erection of a lavatory for men only at a cost of £1800.

WOLVERHAMPTON.—The Public Works Committee invite designs and tenders for motor vans for street scavenging and the conveyance of road materials. Outline specification and form of tender can be obtained on application to Mr. J. W. Bradley, C.E., Borough Engineer and Surveyor, Town Hall, Wolverhampton, firms tendering to do so at their own cost in every respect.

LEITH.—For the year 1897 the deaths in the burgh of Leith numbered 1511—males, 762; females, 749; being equivalent to an annual death-rate of 20 per 1000. The deaths from infectious diseases numbered 212, including 92 from measles, and 68 from whooping-cough. The new infectious cases notified under the Notification Act totalled 640—typhoid, 56; small-pox, 3; scarlet fever, 412; diphtheria, 71; membranous croup, 7; erysipelas, 86; puerperal fever, 4; continued fever, 1. 384 cases, including measles (49) and probationary cases (10), were removed to Leith Public Health Hospital, East Pilton. According to the figures given, by far the most fatal of the infectious diseases during 1897 were measles and whooping-cough, which between them killed 161 persons, mostly children—that is, over three times as many as died from all the other infectious diseases put together.

GRAVESEND.—Formal sanction has been received from the Local Government Board for the loan of £121 for a mortuary.

DARWEN.—The Health Committee has decided to obtain tenders for providing different makes of destructors for house refuse.

CIRENCESTER.—The Rural District Council has agreed to an arrangement with the British Institute of Medicine to examine bacteriologically and report upon morbid products in doubtful cases of diphtheria and typhoid fever at a charge of 2s. 6d. each.

COLWYN BAY.—Fresh plans of the proposed infectious hospital have been forwarded to the Local Government Board. The cost is allocated as follows:—Hospital buildings, £795; administrative cottage, £585; laundry, mortuary, and disinfecting apparatus, £390; fencing in site, £280; cost of site, £450. Total, £2500.

SHREWSBURY.—The Local Government Board inquiry in reference to the proposed river water scheme for the borough of Shrewsbury was resumed on the 31st ult. The Chairman of the Finance Committee said the cost of the proposed river scheme would be £48,000. In the event of the adoption of an efficient scheme certain economies and other savings could be effected, which would save £2081 per annum in the present working expenses. This would enable the Corporation to borrow £40,000 at 3 per cent., repayable in thirty years, without any increase in the rates. Mr. G. F. Deacon, civil engineer, gave evidence in support of the Church Stretton scheme. He estimated the total at £106,000. The inquiry was again adjourned.

LIVERPOOL.—Mr. George Johnson, senior Inspector in the Sanitary Department of the Corporation of Liverpool, in whose employ he has been for forty-four years, was last week, on retiring from the service, presented by his late colleagues with a handsome marble timepiece and vases. For no less than thirty-two years Mr. Johnson has laboured in the sanitary reformation of Liverpool. His knowledge and experience of things as they were in the birth and infancy of public health work is in a way unique, and many an interesting and even thrilling chapter of reminiscences has he related to his *confrères* of a later and more prosaic age, which, could they be perpetuated in print, would add an uncommon chapter to the early history of the sanitary service. Liverpool has been a training school for Inspectors, and probably no man has given more initiatory lessons to Sanitary Inspectors than the subject of our notice. Having regard to the fact also that in his work he made no enemies but many friends, and was ever a *persona grata* among his wide circle of present and former colleagues, it was fitting that the official close of such a useful and honourable career should be recognised with more than words, good as are the congratulations of one's friends. The testimonial fund was warmly supported, and Inspectors N. Coates and J. Cangley, with Messrs. Dillon and Jenkins, of the clinical department, were delegated to make the presentation at Mr. Johnson's home. Messrs. Coates and Dillon feelingly voiced the admiration and goodwill of the subscribers towards Mr. Johnson, who suitably replied and thanked them for their great kindness. Our best wishes go with the veteran in his well-earned retirement.

HUNTINGDONSHIRE.—Mr. D. M. F. Gaskin, M.I.C.E., of Liverpool, has been retained by the Council to investigate the water supply of the district.

THETFORD.—The water from the Thetford Water Works has just been analysed, and found to be entirely free from sewage or drainage impurities, and is an excellent water for drinking purposes.

BISHOP AUCKLAND.—The Urban District Council has instructed Mr. D. Balfour, M. Inst. C.E., Newcastle-on-Tyne, to report as to new filter beds proposed at the waterworks for the supply of the town of Bishop Auckland.

SCARBOROUGH.—A special meeting of the Sanitary and Lighting Committee was held recently to further consider the question of a site for the proposed destructor. Messrs. Barr, Hirst, Levitt, and Smith presented a copy of the resolution passed at a previous meeting, together with a petition against the erection of the destructor in the Old Gaol buildings, signed by 500 ratepayers. After some discussion it was decided that all the members of the Town Council should visit Bradford to inspect the Horsfall destructor erected on the Hammerton-street site. It was further decided to inspect the refuse destructor at Cambridge early in the new year.

CLOUGHTON.—Cloughton, near Scarborough, where is situated the country and marine residence of the late Sir Frank Lockwood, Q.C., M.P., is highly dissatisfied with its water supply, which is now in the hands of a company. At a public meeting of the inhabitants, held recently, Mr. W. C. Allanson, a prominent ratepayer, said that he had not a plentiful supply in his house, and what there was stank. He could show any of the directors a glass of water which was as red as a fox and unfit for any person to drink. Some of the pipes now in use were put down in 1874, and they were only old gas pipes. The Duchy of Lancaster, who own most of the land and property here, only required £10 for a spring, and what was that amount when a supply of good water was in question? It was resolved to ask the District Council to take the necessary steps to procure an adequate supply of pure water.

Personal.

DR. L. ROBERTS has been appointed Medical Officer for the district of Caerwys.

MR. W. B. HARMER has been re-elected Sanitary Inspector for the rural district of Circencester.

DR. C. E. PATERSON has been appointed Medical Officer for the Frimley district of Farnham Union.

DR. DENING has been reappointed Medical Officer, and Mr. J. Vann, Inspector of Nuisances, for the district of Stow-on-the-Wold.

THE salary of Mr. Stilgoe, the Borough Surveyor for Dover, has been raised by £100 per annum, the increase to commence from October last.

IT is proposed to appoint Mr. W. A. Chamen, chief assistant to the Crompton Company, London, as Electrical Engineer under the Glasgow Corporation, at a salary of £800 per annum.

Dr. O. GETHIN JONES, M.D., has been appointed Medical Officer for Porthcawl.

DR. GEPP has been appointed Medical Officer of Health for the district of Newport.

MR. A. GARDNER has been appointed Medical Officer of Health for the rural district of Kirkley Moorside.

MR. E. H. HOUFTON has been appointed Medical Officer of Health for the urban district of Mansfield Woodhouse.

THE Local Government Board has sanctioned the appointment of Dr. F. E. Streeter as Medical Officer of Health for New Swindon, at a salary of £100 per annum.

Sewerage Schemes.

[TO MUNICIPAL ENGINEERS AND SURVEYORS.—The Editor will be pleased to receive items for publication relating to sewerage schemes projected or inaugurated, together with explanatory diagrams or photographs. The former should be drawn and lettered in black ink.]

THE Surveyor for Dunstable is preparing plans of the land available for irrigation by gravitation on the Luton-road site.

THE Thames Board of Conservators is forcing a drainage scheme on Wendover, and Mr. Fawcett has prepared a scheme, costing £2000.

THE specifications for the sewage outfall works at Buckfastleigh are to be passed, subject to any alterations the committee might make, and it has been decided to invite tenders.

AT the last meeting of the Baildon District Council it was agreed to apply to the Local Government Board for sanction to borrow an additional loan of £350 for works in connection with the sewerage of Tong Park.

THE Uxbridge Urban District Council has received formal sanction to the borrowing of the sums of £4397, £12,647, £5568, and £12,210 for purposes of sewerage and sewage disposal for the parishes of Cowley, Hillingdon East, West Drayton, and Yiewsley respectively. The consideration of the Hayes drainage has been postponed.

THE Town Clerk has written the Rural District Council of Guildford in reference to the proposal that the sewage of Stoke-next-Guildford should be received at the borough outfall works, that as the district had been enlarged since the commencement of the negotiations it appeared to the Council to be most important, and to the interests of all parties, that the sewage likely to come from Stoke should be properly treated at the borough outfall works. The Town Council therefore proposed to consult an expert on this point, and on the general management of its works, and pending this report the Council could not give the Rural District Council any more definite reply to the inquiry addressed to . The letter was referred to the Drainage Committee.

THE Eton Urban District Council has decided to apply for a loan to carry out the new system of drainage which it is proposed to adopt.

THE Dawlish Urban District Council has appointed Mr. T. Pearse, of Plymouth, as Clerk in connection with the new sewerage scheme, at a salary of £2 10s. per week.

MR. SIMPSON, Engineer, has presented to the Barrow Urban District Council a sewerage scheme, the cost of which is estimated at £4750. The matter has been referred to the Syston Parish Council for consideration.

THE Guildford Rural District Council has accepted the tender of Messrs. Streeter Brothers, for the carrying out of works of sewerage and sewage disposal at Shere, at £909; and has decided to apply to the Public Works Loan Commissioners for a loan of £950 for the work.

A DECISION of much importance to Local Authorities has just been communicated by the Local Government Board in Church District Council. Thousands of pounds have been spent in the equipment of Accrington and Church outfall sewage works, but land filtration is not included, and the Local Government Board has intimated that no borrowing powers will be sanctioned for the construction of sewers in the district emptying into these works.

A LOCAL Government Board inquiry has been held at Old Hill into an application made by the Rowley Regis District Council to borrow money for the purpose of connecting houses with the sewers. Mr. Bassano explained to the Inspector that a general system of drainage was being carried out throughout the parish, and the Council was desirous of obtaining a loan for £15,000 for the purpose of making house connections. At Tividale the connection had been made to the whole of the houses, excepting about twenty, and progress was being made with the work in other parts of the parish.

THE Local Government Board has written the Honiton Rural District Council stating that it had been advised that the drainage scheme was unsatisfactory in many respects, the chief of which were (1) That the filter effluent was proposed to be discharged into the river without previous treatment on land; (2) that no provision was made for thoroughly examining the existing sewers and remedying their defects, and providing means for inspection, ventilation, and flushing; and (3) that it was not proposed to connect the two existing sewers so as to form one system. The Board considered that whatever process of tank treatment was adopted, sewage should be purified by irrigation on an adequate area of suitable land before the effluent was discharged into a river. It was, therefore, suggested by the Board that the matter should be re-considered with a view to the preparation and submission of a fresh scheme, which would make provision for the treatment of the sewage on the lines indicated.

A DEPUTATION from the Corporation of Manchester visited Glasgow recently and inspected the Dalmarnock sewage works.

A LOCAL Government Board inquiry has been held at Padiham into the Council's application to borrow £10,151 for works of sewerage, and for the erection of a river wall and boundary walls at the storeyard.

THE Hungerford District Council and Parochial Committee have decided to adopt Mr. Hives's scheme for the drainage of the town. It has been decided by the Parish Council to convene a meeting for discussing the subject.

THE Swindon New Town Urban District Council has decided to construct the two acres of artificial filtering beds at the sewage farm at an estimated cost of £2500, which work the Council will carry out itself under the direction of the surveyor, Mr. H. J. Hamp.

THE Sanitary Committee of the Leatherhead District Council has been directed to prepare an estimate of the cost of adopting the Congleton system of sewage treatment, by which Mr. Pott believes a saving of between £200 and £300 a year will be effected.

A MEETING was held recently at Corsham for the purpose of taking into consideration the two schemes of drainage for Pound Hill, the first involving the expenditure of £2500, and the second £698. After a long discussion it was decided to call a parish meeting to further investigate the matter.

THE Urban Council of Aylesbury has agreed that no system of sewage disposal, bacteriological or otherwise, will be satisfactory until the storm water is separately treated. Mr. Locke showed that 114 million gallons of storm water passed through the sewage works annually, and the extra cost of pumping involved was £450. A special drain to cost £4000 would, he thought, reduce the quantity by one-half.

A LOCAL Government Board inquiry has been held at Urmston into the application of the Urmston District Council to borrow £2270, and of the Barton District Council to borrow £1130 on behalf of the parish of Flixton. The joint sewerage district was constituted twenty years ago, and the sewage works have been in existence about fifteen years. Settling tanks are to be provided in order to ease the land. The population of Urmston is now about 10,000, and is rapidly increasing, and the rateable value amounts to £26,600. Mr. C. C. Hooley, surveyor, who gave details of the works proposed to be carried out, said there was only one manufactory in the district, and no effluent from breweries or dye works had to be dealt with at the works. After treatment the effluent from the sewage works was passed into the Ship Canal.

Lighting.

OWING to boisterous weather on the west coast of Scotland the electric light has been damaged.

THE Town Council of Bury St. Edmunds has resolved to apply to the Local Government Board for power to borrow £29,000 to carry out electric lighting.

THE Crewe Town Council has decided to apply to the Board of Trade for a Provisional Order authorising it to supply a system of electric lighting for the borough.

A LOCAL Government Board inquiry has been held at Portsmouth into the application of the Corporation for permission to borrow £21,000 for purposes of electric lighting.

THE Lighting Committee of the Dumfries Town Council has resolved to experiment on two lamps with the apparatus for supplying a gallon of hot water for a halfpenny in the slot.

THE ratepayers of River recently polled on the question whether the Lighting and Watching Act, 1833, should be adopted by the parish. The voting resulted in a tie, and consequently the proposal was defeated.

A LOCAL Government Board inquiry has been held at Salford into the application of the Town Council for sanction to borrow £13,000 for purposes of electric lighting. It is proposed to extend the electric cables, and erect a cumulative station under the Regent-road Baths.

(*To the Editor of* THE SANITARY RECORD.)

LEEDS SANITARY CONGRESS — SURCHARGE OF DELEGATES' EXPENSES.

SIR,—At the commencement of the present year application was made to my Authority to appoint representatives at the forthcoming Sanitary Congress, which it was proposed at the time to hold at Leeds in the month of September. The Health Committee thereupon duly appointed the chairman and myself as delegates, and the resolution was duly placed on the agenda book in the form of a minute of committee, which was subsequently confirmed by the Council. In accordance with this resolution, the delegates in due course attended the Congress at Leeds, and the accounts for out-of-pocket expenses were submitted to a subsequent meeting of the Committee. In the meantime the Local Government Board auditor visits the district for the purpose of making his annual audit of the Local Authority's books, and in due course promptly surcharges the members of the Council (who signed the cheque) with the amount paid to

the surveyor and gas engineer (two separate officers) for expenses incurred in attending meetings of the Gas Institute and Municipal and County Engineers' Association held at London and Brighton. He has also intimated his intention of surcharging any similar account, as he contends that such expenditure is illegal, so far as officers are concerned, the conference regulations only applying to the clerk, and the amount allowed under those regulations to the members of the committee and their clerk is only 7s. 6d. per diem, and 15s. per night when away from home on *legal* journeys.

Can any of your numerous readers inform me where district (Local Government Board) auditors have adopted a similar course of action, or where I can find the details of accounts which are "contrary to law," and which, I take it, is the basis of all surcharges?

If this course is to be adopted by Local Government Board auditors throughout sanitary districts generally, I am afraid the delegates from Urban and Rural Authorities at forthcoming Sanitary Congresses will be very few.

I may say the Health Committee are quite willing to pay the expenses of their delegates, but cannot see their way to pass the account under the circumstances, as the amount would have to be refunded to the chairman of Council and Finance Committee at the next annual audit.

SANITARY CONGRESS DELEGATE.

December 28th.

Obituary.

DR. MONTGOMERY WARD.

WE regret to announce the death of Dr. Montgomery Ward, which occurred suddenly on Thursday morning, December 30th, at his residence at Rathmines. The deceased gentleman had been suffering from influenza for over a week, but the immediate cause of death was heart failure. The deceased surgeon was a highly respected and much esteemed member of the medical profession, in which he occupied a foremost position. For many years he was Medical Officer of Health to the Rathmines Town Commissioners, and he enjoyed a large and fashionable practice in the township. He was recently elected Visiting Surgeon to Mercer's Hospital, in succession to the late Surgeon O'Grady, whom he has not long survived.

A LOW DEATH-RATE. — At a meeting of the Eastbourne Town Council on Monday, the Chairman of the Sanitary Committee (Alderman Nevill Strange) called attention to the fact that during the past year there had been only 300 deaths in the borough, including deaths of visitors and deaths in the hospital and workhouse. This brought the death-rate down to 8·86, or, if they excluded non-residents, 7·6. In 1888, when the population of the town was 28,000, the deaths were only one or two short of 400. Now the population was 43,000. Improved sanitary appliances and regulations had greatly conduced to the health of the borough.

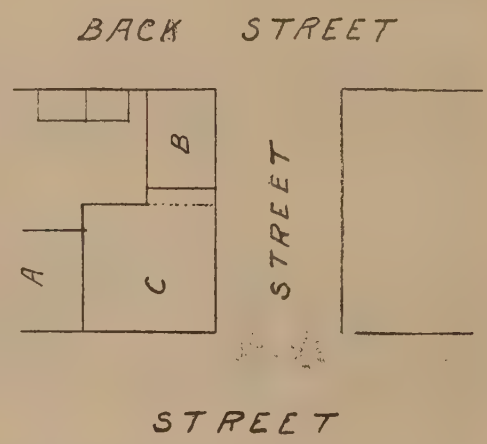
Notes and Queries.

[Subscribers have the privilege of obtaining advice in this column on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed to THE EDITOR, "Notes and Queries," THE SANITARY RECORD, 5, Fetter-lane, London, E.C 1

NOTE.—If an answer be required immediately, a stamped addressed envelope must be enclosed, when we will endeavour to furnish a copy of the answer by post, as owing to the large number of queries received we cannot guarantee the insertion of a reply in the succeeding issue.

921.—BUILDING BYE-LAWS: NEW BUILDING AT CORNER OF TWO STREETS.—"J. E." writes:—"I submit plan showing properties A, B, and C. It is proposed to erect a cottage and shop on C, part of which site is at present covered with an old cottage, which will be pulled down. There is one privy for the three cottages. The yard shown is common to A and C. There is a covered passage between C and B, as shown. It would be impossible to get 10ft. of space, extending laterally throughout the entire width of the building, without taking it from cottage B. What is meant by width in the last paragraph? What is usually done in such cases of corner buildings? I enclose a copy of the bye-laws in force."

Answer.—The bye-laws of this Council require a space of not less than 150 square feet at the rear of a new domestic building, such space to belong *exclusively* to such building, and to be free from any erection above the level of the ground, except a water-closet, earth-closet, or



privy and ashpit. Such space is to extend laterally throughout the entire width (that is, from party wall to party wall, or where there is no party wall, to the outside gable wall or walls), and is not to be less in any case than 10ft. If there cannot be provided an open space exclusively belonging to the proposed new domestic building, such space to have a depth of not less than 10ft. and a width equal to the whole width of the building, the proposed building cannot be erected in conformity with the existing bye-laws of the Council. In the building bye-laws of some Local Authorities, a proviso is often made for dealing with the re-erection of buildings on sites where two streets meet at right angles, and a modification of the bye-law as to open space at rear is provided for, it being accepted that the two streets afford the necessary means for securing the required cross ventilation of the buildings. In such a case, however, a sufficient space to the rear should be secured for the purposes of a closet and ashpit, and it is also essential that the proviso

should be limited to cases in which there is a passage leading from the space at the rear into one of the adjacent streets. Additional information on this subject may be obtained from Knight's "Annotated Model Bye-laws of the Local Government Board," 5th edition, price 12s. 6d., which should be in the hands of all surveyors whose duty it is to interpret and see to the execution of such bye-laws. A Local Authority are not enabled to enforce the provision of a separate water-closet or privy for every individual house built or rebuilt. Sec. 35 of the Public Health Act, 1875, which governs the case, provides that it shall not be lawful newly to build or rebuild any house without a sufficient water-closet, &c., but it does not require a separate water-closet for every individual house build or rebuilt. If the Authority are of opinion that one water-closet will be sufficient for three houses they may approve the plans, but if they deem the provision insufficient they must proceed under Sec. 36 of the Public Health Act, 1875.

922.—Steam: Latent Power of: Books Recommended.—"P. M." writes:—"What is the latent heat of steam? How many units?"

Answer.—The latent heat of steam at atmospheric pressure is 966·6 units. In other words, it requires 966·6 British thermal units of heat to convert 1 lb. of water at 212 deg. Fah. into steam at the same temperature, or 1 lb. of steam at 212 deg. Fah. gives out 965·6 units of heat in being condensed into water at the same temperature. By latent heat is meant the quantity of heat which must be communicated to a body in a given state in order to convert it into another state without changing its temperature. Engineering students who require an elementary manual on this subject should procure Ripper's "Steam," in Longman's Elementary Science Manuals, which is one of the most lucid manuals on steam of which we are aware. A more advanced book is Jamieson's "Text-book on Steam and Steam Engines," price 7s. 6d. (C. Griffin and Co., Ltd.), which is also an excellent book.

923.—Canal Boats Acts: Cubic Space to be Provided in Cabins.—"M. P." writes:—"What is the maximum number of adults and children which should be allowed to live in the cabins of canal boats containing respectively 80 cubic feet and 180 cubic feet?"

Answer.—By the General Order of the Local Government Board, dated March 20th, 1878, made under the provisions of Secs. 2 and 9 of the Canal Boats Act, 1877, it is required by Clause 8 that, subject to the conditions prescribed with respect to the separation of the sexes, the number of persons who may be allowed to dwell in a canal boat registered as a dwelling in conformity with the conditions of the Act as to registration, shall be such that in the cabin or cabins there shall not be less than 60 cubic feet of free air space for each person above the age of twelve years, and not less than 40 cubic feet of free air space for each child under the age of twelve years. Provided that in the case of a boat built prior to June 30th, 1878, the free air space for each child under twelve years shall be deemed sufficient if it is not less than 30 cubic feet; and provided also that in the case of a boat registered as a "fly" boat, and worked by shifts by four persons above the age of twelve years, there shall not be less than 180 cubic feet of air space in any cabin occupied as a sleeping-place by any two of such persons at one and the same time. From this it will, therefore, be seen that in a cabin containing 80 cubic feet of free air space, one person only above the age of twelve years, or two persons under this age, should be allowed to sleep therein, and that in a cabin containing 180 cubic feet of free air space there should not be allowed more than three persons above the age of twelve years. If, however, the boat be used as a "fly" boat, the cabin will provide sleeping accommodation for four persons, but it must not be occupied as a sleeping-place by more than two persons at one and the same time. The cabin may also be lawfully occupied by two adults and one male under fourteen, or one female under twelve years of age. Taylor's "Sanitary Inspector's Handbook," price 5s., contains much information on the Canal Boats Acts, which would be useful to our correspondent.

924.—Self-Cleansing Velocity in Sewers and Drains.—"M. P." writes:—"At what speed ought the sewage to flow in a 4in. drain to render it self-cleansing, and also in a 15in. drain?"

Answer.—In order to prevent deposit in sewers and drains below 9in. in diameter, and so that they shall therefore be self-cleansing, a velocity of not less than 3ft. per second should be produced when running full or half-full, and sewers from 12in. to 24in. in diameter should have a velocity of not less than 2½ft. per second. Inasmuch, however, as it is impossible to provide for drains or sewers always running full, and as, with a reduced depth of sewage, there is greater friction and a retardation of the velocity, allowance must be made for such, and a greater fall must be given to sewers and drains in practice than that which gives a velocity of 3ft. or 2½ft. per second, as the case may be. A safe rule to adopt is that known as Maguire's, or the decimal rule, for gradients to produce a self-cleansing velocity, which is, for

4in. drains, a fall of 1 in 40,
6in. drains, a fall of 1 in 60,
9in. drains, a fall of 1 in 90,
12in. drains, a fall of 1 in 120.

Spinks' "House Drainage Manual," price 5s., will be found helpful on the subject.

925.—Provisional Orders: Definition and Scope of.—"Surveyor" writes:—"Will you be good enough to explain what is a Provisional Order, and for what purpose may Provisional Orders be obtained?"

Answer.—Probably the best definition of a Provisional Order is that given by the Master of the Rolls in the case of Morley *in re* 32 L. T. (N. S.) 524, referring to a Provisional Order made by the Board of Trade, as follows:—"The Legislature, instead of allowing proceedings to be taken before a Committee of either House, decided that these inquiries (*i.e*, preliminary to the making of the Order) might be prosecuted more cheaply and more beneficially before a local tribunal or persons appointed to inquire into the matters locally. These proceedings are instituted, and the parties interested, instead of applying to Parliament, apply to the Board of Trade, and after making a proper investigation in the locality, the Board of Trade makes a Provisional Order, and then, if Parliament thinks fit, that Provisional Order, generally with a great many more, is confirmed by an Act, which is not procured at all by the applicants, but by the Board of Trade, that is, by the executive Government of the country. The result is that there has been an entire change of system, and all that the applicant obtains is the Provisional Order, and there is no proceeding in Parliament with which he really has anything to do *directly*.

The Board can exercise their discretion as to submitting the Order to Parliament at all, and consequently as to when they will do so. They generally group together several Orders in one Bill, in such a manner as to prevent, as far as practicable, unopposed Orders from being delayed by the companionship of such as may be contested. They can choose in which House to bring in the Bill, and accordingly at the latter part of the session they frequently introduce it in the House of Lords.

As most Provisional Orders are made for the benefit of some particular locality, and are not framed by the Local Government Board spontaneously, if opposition be made to the Order, its defence before the Committee is left to the promoters of the proposition contained in the Order, notwithstanding the observations of the Master of the Rolls cited above.

The Local Goverment Board issue a circular about the end of August every year, in which days are prescribed, usually about the 15th of December, for the sending in of applications for Provisional Orders to them.

Power to make Provisional Orders.—The Local Government Board have power to make Provisional Orders with regard to the following subjects :—

Artisans' and labourers' dwellings *i.e.*, for the confirmation of any improvement scheme of a Local Authority under the Artisans' and Labourers' Dwellings Improvements Act, 1875, Sec. 6.

Compulsory purchase of lands, *i.e.*, for empowering a Local Authority to put in force the powers of the Lands Clauses Consolidation Acts with respect to the purchase of lands otherwise than by agreement, under the Public Health Act, 1875, Sec. 176.

Confirming Acts, *i.e.*, for repealing, altering, or amending any Act by which a Provisional Order has been confirmed, Sec. 297.

Expenses, *i.e.*, for enabling an Urban Sanitary Authority whose expenses were payable at the time of the passing of the Public Health Act, 1875, otherwise than in the manner provided by the Local Government Acts, to defray their expenses out of a district fund and general district rate, levied under the Public Health Act, 1875, Sec. 208.

Gas, *i.e.*, for enabling an Urban Sanitary Authority and a Rural Sanitary Authority invested with urban powers, to supply their district with gas, under the Public Health Act, 1875, Sec. 161, and the Gas and Waterworks Facilities Act, 1870, Sec. 4.

General district rates, *i.e.*, for dealing with exemptions of property from assessment to general district rates, under the Public Health Act, 1875, Sec. 211.

Improvement Act districts, *i.e.*, for the dissolution of any such district within a borough, and the transfer of the jurisdiction and powers of the Improvement Commissioners to the Council of the borough, Sec. 270.

Joint Sewerage Boards, *i.e.*, for dissolving the district of such a Board, or for constituting such a district a united district subject to the jurisdiction of a joint Board, in manner provided by the Public Health Act, 1875, Sec. 323.

Local Acts, *i.e.*, for repealing, altering, or amending any local Act other than an Act for the conservancy of rivers in force in the district of any Local Authority, and which does not confer powers or privileges on any persons or person for their or his own pecuniary benefit, and which relates to the same subject matters as the Public Health Act, 1875, Sec. 303.

Local government districts, *i.e.*, for constituting a local government district and dividing the same into wards, Sec. 271; for dividing such a district already constituted into wards, or for abolishing or altering the wards into which such a district has been divided by a Provisional Order, *ib.*, Schedule II., Part I., r. 6; for dissolving or altering such a district, Sec. 270.

Main sewerage districts, *i.e.*, for dissolving such a district constituted under the Public Health Act, 1848, or for constituting such a district a united district subject to the jurisdiction of a joint board, in manner provided by the Public Health Act, 1875, Sec. 323.

Orders in Council, *i.e.*, for repealing, altering, or amending any Order in Council, made in pursuance of any of the Sanitary Acts, Sec. 297.

Port Sanitary Authorities, *i.e.*, for constituting such Authorities, Sec. 287.

Special drainage districts, *i.e.*, for dissolving any such district, and merging it in the parish or parishes in which it is situated, Sec. 270.

Transfer of powers, &c., *i.e.*, for settling any doubt or difference, and adjusting any accounts arising out of or incidental to any powers, rights, duties, capacities, liabilities, obligations, and property, or any of them, at any time transferred, or alleged or claimed to be transferred in pursuance of the Public Health Act, 1875, or any Provisional Order made thereunder, from or to any Authority or arising out of or incidental to the transfer thereof. Sec. 304.

Union of districts, *i.e.*, for forming any urban or rural districts, or contributory places in any rural districts, into a united district for (1) the procuring a common supply of water, (2) the making a main sewer or carrying into effect a system of sewerage for the use of all such districts or contributory places, or (3) for any other purposes of the Public Health Act, 1875, Sec. 279.

With respect to Provisional Orders authorised to be made by the Local Government Board under the Public Health Act, 1875, Sec. 297 of that Act provides :—

(1) The Local Government Board shall not make any Provisional Order under this Act unless public notice of the purport of the proposed Order has been previously given by advertisement in two successive weeks in some local newspaper circulating in the district to which such Provisional Order relates.

(2) Before making any such Provisional Order, the Local Government Board shall consider any objections which shall be made thereto by any persons affected thereby, and in cases where the subject matter is one to which a local matter is applicable, shall cause to be made a local inquiry, of which public notice shall be given in manner aforesaid, and at which all persons interested shall be permitted to attend and make objections.

(3) The Local Government Board may submit to Parliament for confirmation any Provisional Order made by it in pursuance of this Act, but any such Order shall be of no force whatever unless and until it is confirmed by Parliament.

(4) If while the Bill confirming any such Order is pending in either House of Parliament, a petition is presented against any Order comprised therein, the Bill, so far as it relates to such order, may be referred to a Select Committee, and the petitioner shall be allowed to appear and oppose, as in the case of private Bills.

(5) Any Act confirming any Provisional Order made in pursuance of the Sanitary Acts, or of this Act, and any Order in Council made in pursuance of any of the Sanitary Acts, may be repealed, altered, or amended by any Provisional Order made by the Local Government Board and confirmed by Parliament :

(6) The Local Government Board may revoke, either wholly or partially, any Provisional Order made by them before the same is confirmed by Parliament, but such revocation shall not be made whilst the Bill confirming the Order is pending in either House of Parliament.

(7) The making of a Provisional Order shall be *primâ facie* evidence that all the requirements of this Act in respect of proceedings required to be taken previously to the making of such Provisional Order have been complied with.

(8) Every Act confirming any such Provisional Order shall be deemed to be a public general Act.

Contracts Open.

The dates given below are the latest up to which tenders can be received.

BRADFORD. — January 8th. — Electric Lighting. — Messrs. Milnes and France, architects, 99, Swan Arcade, Bradford.

LIMERICK.—January 11th.—Water-closet, &c.—Mr. Wm. E. Corbett, C.E., city surveyor, 28, Glentworth-street.

LONDON, N.—January 11th.—Sewer.—Mr. C. G. Lawson, Surveyor to the Southgate Urban District Council.

KINGSTON-UPON-THAMES. — January 12th. — Sewer. —The Borough Surveyor, Clatteen House.

PAINSWICK (NEAR STROUD). — January 12th.—Removal of Refuse.—Mr. Fredk. Winterbotham, clerk to the Rural District Council, John-street, Stroud.

NOTTINGHAM.—January 13th.—Lighting Requisites. —Mr. Rhodes, lighting inspector, St. John's-street.

HAYES (MIDDLESEX).—January 13th.—Sewer.—Mr. Bertram Freeman, 24, New Windsor-street, Uxbridge.

SHERBURN (DURHAM).—January 14th.—Sewer, &c. —Mr. George Gregson, Surveyor to the Council, 43, Western Hill, Durham.

STANLEY (DURHAM).—January 14th-17th.—Sewer.— Mr. Jos. Routledge, surveyor, Council Offices.

NEWMARKET.—January 19th.—Sewer, &c.—Mr. T. W. Metcalf, Town Hall, Newmarket.

Vacancies.

BOROUGH SURVEYOR (STOCKTON-ON-TEES, January 20th).—For the Corporation. Salary, £350 per annum. Mr. Mat. B. Dodds, town clerk, Stockton-on-Tees.

CITY ENGINEER (LIVERPOOL, January 18th).—For the Council. Salary will commence at £1000 per annum. Town Clerk, Municipal Offices, Dale-street, Liverpool.

ENGINEER (NEWTON ABBOT, January 11th).—For the Guardians of Newton Abbot Union. Salary, 30s. per week, subject to the deductions under the Poor Law Officers' Superannuation Act, 1896. Mr. John Alsop, clerk, Union Offices, Newton Abbot.

PART 1 OF NOTES ON

Practical Sanitary Science.

BY WILLIAM H. MAXWELL,

Author of Drainage Work and Sanitary Fittings, &c.

FORMING A COMPLETE TREATISE UPON

VENTILATING, LIGHTING, & HEATING.

PRESS OPINIONS.

"An entirely useful book, being both lucid and condensed, and the diagrams and illustrations are excellent. It is fully up to date, and well supplied with references, and as a text book is admirably suited to the needs of those for whom it is intended."—*The Hospital.*

"The book will not only be useful to candidates for examination, but also to busy men in practice who desire a summary of the chief points to be observed in carrying out any schemes of ventilation, lighting, and heating . . . the book is well illustrated and clearly printed."—*The Surveyor.*

Now Ready. Price 2s. net. Demy 8vo., Cloth, Gilt, 50 pp. With Numerous Diagrams.

Calculation of Areas, Cubic Space, etc.,

BEING PART II. OF

Notes on Practical Sanitary Science.

BY WILLIAM H. MAXWELL,

Author of Drainage Work & Sanitary Fittings, &c.,

PRESS OPINION.

"The 'Notes' will, we believe, be found to be of use also to engineers and surveyors in practice, being prepared in a concise form and of ready reference. Some of the most important theories as demonstrated in Euclid are given, and a passing reference is made to the use of Trigonometry and Logarithms. The concluding chapter treats of the calculation of quantities of earthwork."—*The Surveyor.*

THE

Sanitary Record,

JANUARY 14, 1898.

SMALL-POX AND VACCINATION IN GERMANY.

THE phenomenon of a people numbering over fifty millions, surrounded on three sides by others among whom small-pox is always rife, and yet enjoying an immunity unparalleled in any other country, is one which merits the serious attention of all who are interested in the vaccination question, and indeed in the study of public health. The last official reports on the practice of vaccination, and on the incidence of small-pox, issued by the medical statistical department of the Imperial Board of Health at Berlin, relating to the year 1895, are unusually instructive, bringing out clearly alike the strength and the one weak point of the German system, which dates from the law of 1874. But before discussing the figures it will be well to trace the history of the existing administration to its origin, and to explain the reasons which prompted the enactment of the legislation that has proved such a blessing to the nation. Prior to the Franco-German war of 1870—1, infant vaccination was very general in Germany, as in Great Britain; but the practice there differed very little, if at all, from that in this country, except in the fact that all men who had attained the age of twenty during the preceding twelve months had to present themselves to the military authorities, and those who were accepted, forming from a fourth to a third of the whole number, had to be vaccinated or re-vaccinated before serving their three years in the army. During the war small-pox, breaking out among the Breton recruits, spread throughout the French army, and when the garrisons of Metz, Strassburg, and Sedan, together counting nearly half a million, were carried off as prisoners and quartered in all the principal towns of Germany, the disease spread to the civil population, attacking all ages and both sexes, the German troops and "veterans," or men who had previously passed through the army, however escaping almost entirely. Of the French prisoners over 23,000 died, but of the German army in the field and at home only 226. French refugees sowed in England the seeds of the worst epidemic that had visited this country since the thirties, and the mortality from the same cause was even heavier in Holland. But while Germany suffered severely, more so indeed than this country, it was noticed that in Frankfort-on-Main, where 10,000 French prisoners were quartered, the townsmen escaped almost entirely. What could be the cause? In what respect did the citizens of that ancient Imperial and free city differ from those of other towns? The answer was clear. For forty-five years no child had been permitted to leave school without being re-vaccinated, except when exempted on a medical certificate of unfitness. One of the first Acts passed by the Imperial Parliament in 1874 was to extend to the entire empire the law that had produced such results in Frankfort, and though persons born before 1860 did not come under its operation, the effects of the change were soon manifested. For two or three years, it is true, there was but little small-pox in any of those countries in which the epidemic of 1870—3 had well nigh exhausted the susceptible material, but after that epidemics recurred everywhere except in Germany. While Vienna counted 999 and Prague 637 deaths in a single year, Hamburg and Berlin, Munich and Dresden showed but five or six, and for the last five-and-twenty years small-pox in Germany has been a vanishing quantity, the few cases that do occur being always imported from abroad, while the cases have belonged to the three classes of foreigners—Germans born before 1860, who have contracted the infection from these, or in visits to Russia or France; and unvaccinated children, of whom, owing to the fact that vaccination need not be performed before the end of the year following that in which the infant

was born, there are always over 1½ million. This is the one weak point in the system. The importation will in future be greatly checked by a regulation recently enacted in Prussia, Saxony, and one or two other States, requiring all foreigners from countries where re-vaccination is not compulsory, to submit to vaccination as a condition of domicile, employment, or continued residence in the country, unless they have already had small-pox, or can produce evidence of having been successfully re-vaccinated within the ten years preceding their arrival.

The influence of the neglect of vaccination abroad is seen in the distribution of the disease. Thus, of the 1164 deaths recorded in the last ten years, 919, or four-fifths, have been within a few miles of the frontiers or from the seaports of the North Coast, with a constant floating population of seamen from all nations. Of these 919, the maritime towns furnished 100, the south and west frontier 55, and the east and south-east 764, Russia being the main source of small-pox in Germany, and many outbreaks of the disease in the interior, as that at Berlin in 1895, being no less directly derived from intercourse with abroad. The latest complete and corrected returns are those for 1895, which show a total mortality of 27, against 88 in 1894, and 116 on an average of ten years. Five deaths occurred in Berlin, four in the district of Rybruk, and the remaining 18 were distributed mostly singly among sixteen places. Fourteen deaths were actually on the frontiers, and the five in Berlin, if not others, arose from an infection imported direct from Russia.

Prussia, with its enormous foreign trade and extensive frontiers, naturally suffers most, only fifteen cases having occurred in the other States, with an aggregate population of over 20 millions.

Of the 27 deaths 11 were of infants under two years, and all unvaccinated, seven of children under ten years (three being unvaccinated and four showing no marks), two only were adults under forty years, and one of these contracted the disease while travelling in Russia, and seven were considerably older. Of these one had been re-vaccinated over forty years previously, one had been vaccinated as an infant, fifty years ago, while nothing could be learnt as to the others. The Berlin outbreak originated with an adult man who had returned but a few days previously from a business visit to Russia, and involved altogether ten adults and six infants. Of the former who had been vaccinated or re-vaccinated, all had the disease in a very mild form, and recovered, while of the latter, all unvaccinated, five died, constituting the entire mortality in that city for at least two years. Turning now to vaccination, we find that of 1,677,321 infants born in the preceding year, giving a birth-rate of 33·5 per mile, 1,186,674 were presented for vaccination, and 201,975 = 12 per cent. escaped, with or without medical certificates, and of the possible 1,391,019 liable to re-vaccination 1,143,021 were presented, and only 36,054 = 3·15 per cent. were withheld, the deficit in each sum representing the numbers that had died in the interim.

The percentages of successes in primary vaccinations varied between 99·68 in the province of Schwabe and 92·03 in Lübeck, and of re-vaccinations between 99·63 in the Black Forest and 57·82 in Hamburg. The extraordinary proportion of failures in this city does not reflect on the skill of the operators, but is owing to the far greater permanence of the immunity conferred by the variolo-vaccine produced by L. Voigt in 1881, and, whether passed from arm to arm or for re-inoculation of calves, since used almost exclusively in public and private practice. Nowhere else have the successes ever fallen so low as 90 per cent. when other lymph has been employed.

Eleven deaths were ascribed to vaccination. Of three no information could be obtained; in seven the first signs of inflammation did not appear until the third or fourth week, and were therefore evidently due to some local infection from insanitary surroundings long subsequently to the operation, and in the single case in which the symptoms followed soon after the vaccination the infant's arm had been bandaged by the ignorant parents with a filthy rag (*stark ekelige Lumpe*). Yet in cases—of which, however, there were none in that year—when the inflammary symptoms, or even erysipelas, clearly date from the operation, the poison may, as Dr. Kübler remarks, be derived not from the lymph or the instruments, but from the infant's skin, if that has not been cleansed and sterilised as before other surgical operations. E. W.

Notes.

In the death of Mr. Ernest Hart a singularly active and useful career has been brought to a close. For over thirty years editor of the *British Medical Journal*, a post which he held till his death, he was also associated with other departments of medical journalism, and in this field he was an acknowledged power. But to our readers he will probably be best remembered by the pioneer work which he did for sanitary science, in days when the great movement which has distinguished the second half of this century was but in its infancy, and for his services in this direction his memory will long be cherished. He was chairman of the National Health Society, and of the Smoke Abatement Committee. He succeeded in placing on a satisfactory footing the arrangements for the sick poor in our workhouses, which were formerly notoriously defective; he established societies for the protection of infant life, and took an active share in the framing of the Public Health Acts; he did most valuable work in safeguarding the milk supply of towns; and last, but not least, as editor of the Sanitary Record he was instrumental in spreading the principles of hygiene through every corner of the land. Such a record, which only covers a fraction of the work with which Mr. Hart's name is identified, may well entitle him to the distinction of having been a most useful public servant and a benefactor to his age.

According to the *British Medical Journal*, the new Scotch Public Health Act, which came into operation on the first of this month, places Scotland "distinctly in advance of England in respect of sanitary legislation," but the writer qualifies this statement by the addition that its tendency in several respects is certainly reactionary. The subject is too wide to be enlarged upon in this place, nor have we space in these "Notes" to criticise

as a whole what is now established as the Code of Public Health for Scotland, most of the leading provisions of which, indeed, have from time to time been commented on in these columns during the passage of the measure through Parliament. We note with satisfaction, however, that whatever may be the defects and shortcomings of the Act, Local Authorities in Scotland have begun the new year with laudable resolutions to make the most of it, and to use their new powers to the best advantage for improving the sanitary conditions of their respective districts. They have plenty of work cut out for them to commence with—in framing new bye-laws, in bringing their existing administration into line with the requirements of the new law, and generally in making themselves thoroughly acquainted with all its numerous provisions.

At the meeting of the Educational Institute in Scotland last week a valuable paper on "Health Conditions in Schools" was contributed by Dr. Munro, Medical Officer of Health for Renfrewshire. The writer pointed out that among the larger public elementary schools at least the sanitary conditions had during the last dozen years or so undergone an enormous improvement, though not without a good deal of carping criticism from those ratepayers who view all such improvements in the light of unnecessary extravagance on the part of School Boards. The degree of perfection to which the sanitary arrangements in the principal schools of the larger towns have been carried is a striking illustration of the enlightened spirit in which most School Boards have regarded their responsibilities. But, unfortunately, this tribute of praise must end there. In the smaller schools, and especially in the older ones, the health conditions are still far from what they ought to be. Even allowing for the impossibility of expecting the latest appliances for mechanical ventilation in such buildings, a certain standard of ventilation and cleanliness ought, in the interests of the health of the children, to be maintained; and Dr. Munro gave it as the result of his experience, based on personal inspection over a wide area, that a very large number of schools in the country fell far short of observing such a standard.

It is a matter for some surprise that the Education Department, usually so rigid in their requirements, should view with such tolerance many instances of the most flagrant disregard of the elementary principles of hygiene. But, so far as the schools in Scotland are concerned, we may now expect the dawn of a better era. By the new Public Health Act schools are for the first time specifically brought within the purview of the Local Authority, and there is reason to hope that there will be co-operation between the educational bodies and Sanitary Authorities in establishing a sounder *régime*. It will be in future the duty of Local Authorities to insist upon the proper ventilation and cleaning of all schools under their jurisdiction, and the Act also confers upon them powers in relation to infectious diseases in schools. The problems to be solved are not to be minimised; there are many undoubted difficulties to contend with, but with wise administration and harmonious working we may hope that the smaller schools throughout the country will be brought up to the same sanitary standard that has already been attained in the larger ones.

We observe that the Education Department have resolved to arrange for the examination of candidates for diplomas in cookery. The examinations, which will be held at each recognised training school three times a year, will include, besides practical work, the chemistry of food, adult demonstration, and children's class teaching. This departure will give widespread satisfaction to all who are interested in health in the home; for, among the working classes especially, there is nothing that makes more surely for this end than a sound knowledge of the laws which underlie the preparation of food. Thorough practical teaching is what is required, but to those who would seek to impart it a knowledge of fundamental principles is absolutely essential. The regrettable thing, however, is that, though teachers are not slow to appreciate the advantages of this knowledge, the same cannot be said of those for whom the teaching is really intended; and girls who will one day be wives and mothers often show greater preference for more showy accomplishments than for the art of cookery, probably the most useful of all.

After 230 years of most useful work the City Commission of Sewers has ceased to exist, having now been absorbed in the Court of Common Council. It was pointed out by the chairman at their last meeting, as a somewhat curious coincidence, that the Commission was brought into existence after the Great Fire of 1666, and had to devote its last hours to the consideration of the measures required in connection with the recent disastrous fire in the city, which is considered to have been the greatest fire that has occurred since that historical conflagration. When London had to be rebuilt, on lines that would render such visitations as the plague practically impossible for the future, part of the machinery that was established by Parliament for this great work was the Commission of Sewers, created in 1667, and ever since that date it has pursued the even tenor of its way, until now it has demitted office full of years and honour. The multifarious duties of the Commission in modern times are most inadequately indicated by its rather unsavoury title, for it has not merely had charge of the sewers and the draining and cleansing of the thoroughfares, but it has also been concerned with the lighting and improvement and the general sanitation of the city, as well as many other matters, such as underground locomotion and telephonic communication.

Speaking of "multifarious duties," Mr. Chaplin in his speech at Lincoln the other day, on the work of the Local Government Board, made out a pretty strong representation of the extraordinary number of details of which that hard-working Department is supposed to be cognisant. The mere catalogue of the matters that come under its consideration is apt to bewilder the ordinary mind. The administration of the Public Health Acts, which are sufficiently complex, one would think, to engage the attention of a Department of State by themselves, represents the merest fraction of the work that falls to the lot of the Local Government Board. And every year, with fresh legislation, imposes new duties on the shoulders of the already overburdened

Department, so that no wonder the work at length reached such a state of congestion that reorganisation was found to be necessary. This reorganisation has been successfully carried out, but the day must come when further division of labour and specialisation will be requisite. Perhaps then we shall have a Department of Public Health!

In one of the last letters received from the late Sir Henry Havelock-Allan, written from Bombay, on December 14th last, he alludes to a flying visit he paid to Poona, the centre of the plague district, and says that it is to be regretted that in spite of the superhuman efforts directed by Lord Sandhurst to subdue the plague, it shows no material diminution there. And, again, a Reuter's telegram, dated 6th January, states that the plague returns for Bombay show 142 cases and 105 deaths during the preceding forty-eight hours. It appears, according to the telegram, that the epidemic is now following pretty closely the lines of the original outbreak, and ominous rumours are circulating that unless things improve by the time of the solar eclipse, there will be a serious exodus, and a general suspension of business. This is most disheartening to the gallant band that have been endeavouring to stay the ravages of the disease, and introduce a new sanitary *régime*. It may perhaps come to this, that, as in the case of the Great Plague of London, the drastic but purifying influence of fire may be found to be the only sure remedy. But what ruin and destitution that would occasion!

HEALTH CONDITIONS IN SCHOOL LIFE.

At the twenty-fourth congress of the Educational Institute of Scotland held at Stirling recently, a paper on "Health Conditions in School Life" was forwarded by Dr. Munro, Medical Officer of Health, Renfrewshire, who was unavoidably detained and could not be present. In his absence the paper was read by Mr. Marshall, Airth. The health conditions of our public elementary schools, Dr. Munro wrote, had in the average very markedly improved in the course of the last dozen years, at a cost which the average ratepayer—from whom, however, in this matter he was anxious to dissociate himself—was inclined to regard as extravagant. But on closer observation it would be found that the great advance to which he referred had been in great part confined to the larger schools and larger towns. Certainly in the newer schools in the large towns it would almost appear as if finality had been reached, in so far, at least, as structural health conditions were concerned. But in our smaller schools on the average health conditions left a good deal to be desired, even in the case of newer schools, while in the case of many of the older schools matters were in the highest degree unsatisfactory. This he said as the result of observation of schools over a considerable portion of Scotland and England. The type of schools to which he particularly referred was that which accommodated from 100 to 400 children. Here mechanical ventilation was out of the question, but a certain minimum in the matter of heating and ventilating and cleanliness they were entitled to demand in the interests of health. In view of what one had heard of the excessive and rigid requirements of the Education Department, he who visited the smaller schools of the country stood amazed at the tolerance with which the Department had regarded the most glaring offences against the elementary principles of hygiene. In the past the schools in their every relation had been regarded as under the sole control of the Education Department, and Sanitary Authorities, when they ventured to intervene, had done so with bated breath and humble mien. That matters were not entirely satisfactory had apparently found recognition in high quarters, for the new Public Health Act which had come into operation at the beginning of this year considerably altered the point of view, and it was, indeed, this alteration which had determined his choice of a subject. With attention anew directed to these matters, it was possible that the educational authorities might meet the Sanitary Authorities half way in the advances which these latter bodies were pretty sure presently to make to them. In the Public Health Act of 1897 schools were for the first time specifically brought within the purview of the Local Authority, and it would in future be the duty of that authority to see that the school-houses were properly ventilated and free from overcrowding, were kept in a cleanly condition, and were provided with proper sanitary conveniences. The Act also for the first time dealt with schools in relation to infectious diseases. Proceeding, he described the unhealthy conditions of an average small school of an older date, and pointed out that, even in the somewhat larger school, the result of the efforts made had not been satisfactory. It must be admitted that the problem of heating and ventilating these smaller schools was no easy one, and he offered a few suggestions on the subject. It was singular how far architects of public buildings had been from grasping the fundamental principle that in our winter climate, for efficiency, heating and ventilating must be combined. The solution of the problem in the case of any school depended upon the intelligence with which this principle was applied to the circumstances of the particular cases. In schools the ancient system of hot-water piping along the sides of the room or placed beneath the gratings ought to be disestablished. The fundamental point in any system of heating by hot water or steam, and especially in any combination of heating and ventilation, was sufficient boiler power. He asserted that children caught colds and chills through draughts produced in the effort to mitigate defective ventilation, and that many fatal illnesses resulted in that way. The most serious condition remained behind, and it arose in connection with infectious diseases. There was no doubt that at present school attendance was a dominant factor in the spread of infectious diseases; in the case of scarlet fever less distinctively, in the case of measles and whooping-cough beyond all doubt. The defective ventilation of our smaller schools might not exert a very direct appreciable influence on the health of the children, but he was perfectly satisfied that when an infective subject found entrance to a school the defective ventilation of the school played a considerable part in the spread of the disease. Fresh air was the most effective disinfectant. One other condition favourable to the spread of infectious disease was unhappily too common in our smaller schools—it might be described in gentle terms "insufficient cleanliness." He advocated the more frequent cleaning of school floors, &c., as being essential for the remedy of this evil.

NOTES ON PRACTICAL SANITARY SCIENCE.

By WILLIAM H. MAXWELL.

Assistant Engineer and Surveyor, Leyton Urban District Council, Author of "Drainage Work and Sanitary Fittings," "Ventilation, Heating, and Lighting," &c., Certificates of the Association of Municipal and County Engineers, and Sanitary Institute.

No. 43.—REFUSE DESTRUCTORS.

(Continued from page 9.)

The Borough Engineer of Salford, Mr. Jacobs, designed a furnace for dealing with town refuse and sewage sludge. Its construction was upon the lime kiln principle.[105]

Odgen, of Burnley, introduced a destructor formed with two fires and a boiler over. Among the advantages claimed for it were—the burning of offensive gases by carrying them over a coke fire, and the carbonising of refuse and retention of its fertilising properties.

Amongst the towns which took the lead in the adoption of refuse destructors may be mentioned Manchester, Birmingham, Leeds, Heckmondwike, Warrington, Blackburn, Bradford, Bury, Bolton, Hull, Nottingham, Salford, Ealing, London, and others. The "destructor" has now become very general throughout the country, and numerous furnaces of *recent type* are now either in course or at the point of erection, a destructor in large towns being regarded almost as an indispensable item in the list of municipal contrivances.

The best known destructors of the present day will now be described and illustrated.

Fryer's Destructor.

The general arrangement of the Fryer destructor was patented[106] by the late Mr. Alfred Fryer (of the firm of Manlove, Alliott, and Fryer) in 1876, and is illustrated in the accompanying figures (Nos. 5 and 6):—

This type of destructor consists of a block of cells usually arranged "back to back" in pairs, with a flat top, upon which the house refuse is tipped. Each cell measures internally about 9ft. by 5ft., and is covered by a fire-brick arch 3ft. 6in. high above the grates. The bottom of the furnaces, as will be seen from the illustrations, have an inclination of 1 in 3, from back to front; the rearmost or higher position of which, for a width of 4ft., forms a fire-brick hearth or dead plate, and the lower or remaining part, having a width of 5ft., consists of fire-bars. A wall at the back end of the cells divides each furnace into halves; on one side the upper end of the slope is carried up with a steeper slope to a "feeding hole" for the admission of refuse from above, whilst on the other side is a passage forming an opening into the main flue for the escape of the products of combustion. When the cells are placed back to back with the feed-holes adjoining, only one opening is provided

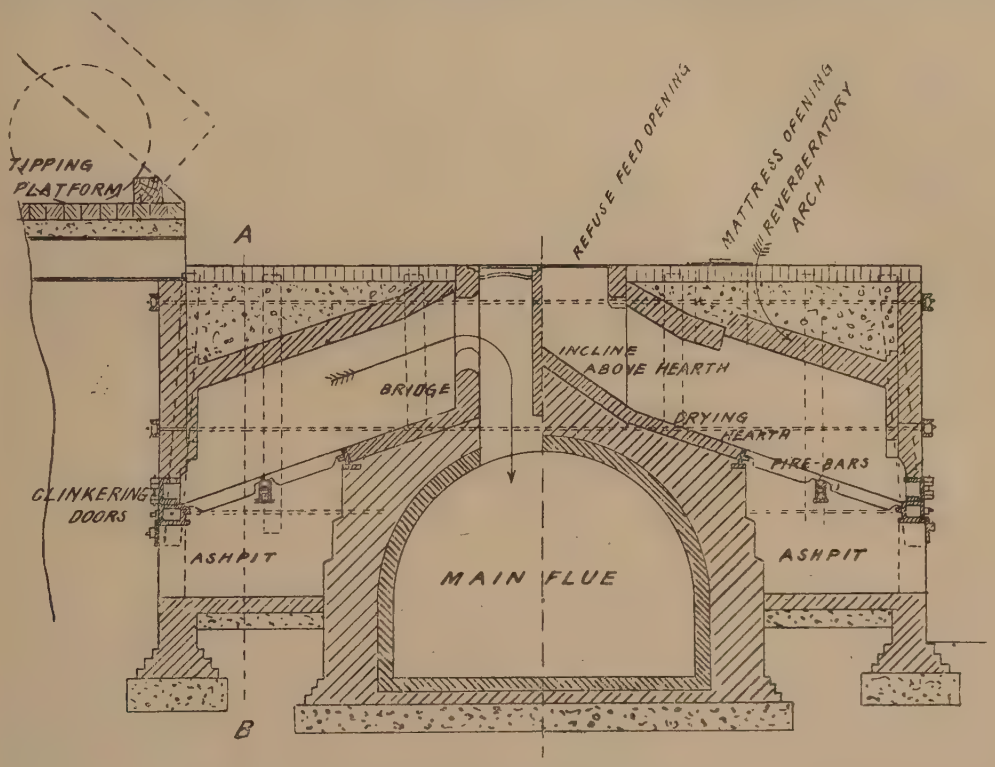

Fig. 5—Section of Fryer's Destructor

[105] "Proceedings" Association Municipal and County Engineers, vol. xiii.

[106] Patent No. 3125, A.D. 1876.

for each pair of cells. The main flue, which is of large size, also forms the dust chamber, and is underneath the hearth. Over the middle of one or more of the furnaces, another opening fitted with a cover is provided and through which infected bedding, condemned meat, &c., can be put into the hottest part of the fire. The space thus provided is not usually large enough to be well adapted for the purpose, as bulky articles—as mattresses, &c.—require to be cut up before they will pass through. The refuse in the cells is moved forwards to the fire-bars by raking from below through the fire door and pushing from above. The clinkering is done at intervals of about two hours or when thoroughly burnt. It is removed from the bars and raised through the burning cinders by means of long iron bars or clinkering tools and raked out of the furnace.

The furnaces have cast iron furnace mouths, with doors 5ft. wide, hinged at the top to open upwards with balance weights.

Both furnaces and flues are, of course, lined throughout with fire-brick.

A group of six cells with their enclosing brickwork forms a rectangular mass measuring about 21ft. by 24ft., and 12ft. high. The refuse arrives at the top of the furnaces by means of an *inclined roadway*, generally built between battering retaining walls, which leads to a platform some 2ft. 6in. above the destructor. This roadway, it need scarcely be mentioned, should be of as flat a slope as can be obtained, and in no case steeper than about 1 in 15. Upon a limited site a *lift* or *elevator* is sometimes used to raise the refuse to the top of the destructor, but a cart road is more satisfactory.

To create a good draught and to carry off all offensive fumes, &c., a destructor *chimney shaft* requires to be from 120ft. to about 200ft. in height, and the lower part is usually finished with a fire-brick lining with a 4½in. air space to a height of from 50ft. to 70ft.

"There is one feature in connection with this form of furnace which militates against its use from the nuisance point of view, and it is this, that the outlets for the products of combustion are at the back, and that, whilst a charge is burning upon the furnace bars the next charge lies upon the dead hearth at the back near the outlet flue, where it undergoes drying and partial decomposition, with the result that offensive vapours are given off, and these pass into the flue without being exposed to sufficient heat to render them inoffensive, and in some cases have produced a nuisance. A second furnace called a '*cremator*'[107] has therefore in many cases been placed in the flue leading to the chimney shaft for the purpose of resolving the organic matters present in the vapour; but the greatly increased cost consequent upon the introduction of the cremator has led to its disuse altogether in some cases."[108]

The following observations as to the general methods of *working* the Fryer destructor apply also, with slight modifications to meet special circumstances, to all destructors, and need not therefore be repeated[109]:—

"The cart, on entering the yard in which the destructor is built, is drawn by a horse up an inclined roadway with varying gradients of from 1 in 12 to 1 in 25, and on arriving at the top a platform is provided with tipping curbs, against which the carts are backed, and their contents are tipped on to the top of the cells. Here the material remains for a short time, until one of the cells is ready for a charge, the charging holes being in direct communication with the fire, but so arranged that very little smoke at any time issues from them. When a cell requires to be charged, the material is shovelled or drawn with a two-pronged rake into and on to the top of the charging hole. A second man stands in line with the opening, and as the material is delivered on to it he pushes it down the incline on to the drying hearth, and continues doing so until the hearth is completely covered. The quantity usually put on at one charge varies from one-third to one-half a cartload, or from 20 cubic feet to 30 cubic feet. From the drying hearth the material is drawn down on the bars as required by the fireman, who stands at a lower level and in front of the furnace. He first clears his fire by pulling the clinker out, spreads the burning material evenly over the fire bars, and then draws down a fresh supply of the partially-dried material from the drying hearth. He usually finishes up by running his bar through the fire, so as to leave as free a passage for the air as possible."

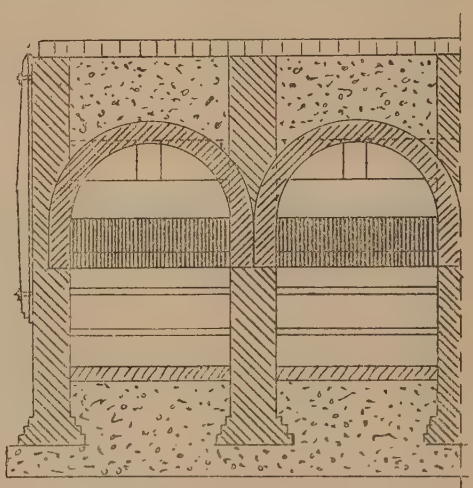

Fig. 6—Fryer's Destructor—Cross Section at A B, Fig. 5

Too much refuse should not be drawn down at once, or the fire will become dead and blackened. Thin layers may be raked down at intervals of about 20 minutes, but the fires should be undisturbed for at least half an hour before clinkering. The fire on the bars (which should always be kept covered) should not be more than about 9in. thick, which is sufficient to secure a clear fire.

"The clinker falls into a barrow provided for the purpose or upon the ground in front of the furnace, where it is cooled by having water from a hose sprinkled upon it. The fine ash drops through the bars into the dust hearth, and it is found that the material in passing through the furnace is reduced to about 25 per cent. of its weight. This residue consists partly of fine ash and partly of clinker, in varying proportions according to the

107 This apparatus will be described in detail later.

108 "Report on Dust Destructors," by the Medical Officer and Engineer (London County Council, May, 1893).

109 Pamphlet on "The Disposal of Town's Refuse," by H. Percy Boulnois, M. Inst. C.E., City Engineer, Liverpool.

character of the material which has been consumed. Whilst the combustion is proceeding, the hot gases from the furnace or cells escape over the bridge into a central flue 6ft. high by 10ft. 4in. wide. This is arranged to prevent too great a velocity from carrying pieces of paper and other unconsumed material to the chimney, and also to allow of the deposit of dust within the flue."

In connection with the Fryer furnace as installed at Ealing, Mr. C. Jones, M. Inst. C.E., has introduced an automatic means of reducing the admission of cold air into the flues, &c., during the processes of feeding and clinkering. "This is done by means of a cast iron hinged door, over the opening entering the dust chamber, attached by a chain to the furnace door, and is so arranged that when the furnace door is open the entrance to the dust chamber has about four-fifths of its area closed; and when the furnace door is shut the flue door is open. This arrangement, being entirely automatic, is quite independent of the attention of the stokers."[110] Also, to reduce the inconvenience of the blowing about of fine dust, a concave water pit is introduced under the fire-bars and into which the ash drops, from whence it is removed in a damp state.

Mr. Stevenson Macadam, Ph.D., F.I.C., &c., as a result of his observations upon this type of destructor, says,[111] there being no forced draught and the supply of air to the cells being entirely dependent upon the suction induced by the chimney shaft, the "general result of working this destructor is that the heats are not sufficient for fully dealing with the combustion of the refuse. There is a tendency for foul smelling gases to pass away unconsumed; for the cinder stage to be only a dull-red heat, and for the clinkering of the residue to be imperfect. I have seen the stuff dragged out of this destructor in an inflaming condition, and the cinder and clinker still glowing and burning, and evolving organic and sulphur gases most abundantly, rendering the atmosphere quite suffocating and nauseous, whilst the fine dust was being blown about all around and over into the neighbouring properties.

"The imperfectly burned gases leaving the Fryer cell, and going by the main flue to the chimney, are supposed to be consumed in the main flue, but unless the temperature there is a full red heat—about 1500 deg. Fah.—these gases cannot be properly burned there. As I have often seen the main flue at a black-red heat, not above 1000 deg. Fah., it was impossible that the organic gases could be rendered innocuous. The deficiency has apparently been admitted at several stations by the construction in the main flue, between the cells and the chimney, of a "*cremator*" where coke is being burned, and the gases travel over the bed of red-hot coke, and are there consumed. In this way the admittedly imperfect combustion of the refuse products in the cells is met by the use of a cremator, which requires extra labour, and involves additional cost in fuel."

STOURBRIDGE. — The Urban District Council has instructed its surveyor to prepare plans for the erection of the new baths.

THE SANITATION OF DOMESTIC BUILDINGS.

By FRANK LATHAM, C.E., M. San. Inst., &c., Assistant Surveyor, Borough of Margate.

CHAPTER II.

SECTION I.

DRAINS are combinations of tubes or pipes, placed in convenient and practical positions, jointed together in such manner as to form water and gas-tight conduits for the purpose of conveying all waste liquids and fæcal matters from our dwellings into a sewer or other suitably constructed receptacle. With house drains the selection of pipes is the first and not the least important matter. This requires a great deal of experience, as there are many points to be observed and considered.

The pipes considered most suitable for house drainage purposes are manufactured from clay, and in the firing are glazed with salt, being known as salt-glazed stoneware pipes.

Stoneware pipes should be well baked, of hard substance, and quite straight, truly concentric in section and of equal thickness throughout, not less than one-twelfth the diameter, and thoroughly glazed both inside and outside. They should be perfectly non-porous, the inside smooth, and free from irregularities. The outside of spigot end should be slightly roughed in the making, to afford a good key to the cement, and the socket should be of sufficient depth to make a good joint, the inside of which being also roughed in the making. The pipe and socket should be made in one piece. The tested pipes manufactured by Messrs. Doulton are known as the standard of what good pipes should be.

Besides Messrs. Doulton and Co., there are other firms recognised as successful manufacturers of stoneware pipes. The Albion Clay Company, Ltd., manufacture the well-known "Granitic" stoneware pipes, which are carefully made and of first-rate quality. These pipes are extremely tough and hard to fracture, and at the same time non-absorbent. The selected pipes, which are stamped "Tested," are very satisfactory for the best class of work, besides being reasonable in cost. Messrs. Craig, Limited, is an old-established firm, and amongst their numerous fire-clay works for which high awards have been given, their glazed drain pipes have received a favourable notice for quality, good shape, and glazing. Their best selected are all that is required. Messrs. Jennings' stoneware pipes, judging from the large amount of work executed in this line by the firm all over the country with the most favourable results, is sufficient proof of the excellency of their manufacture. Messrs. Oates Green, Limited, manufacturers of the "Nalethrie" stoneware, are noted for their "Truinvert" patent pipe, and stand high for the excellency of their materials and workmanship. Messrs. Sankey and Son are the manufacturers of various descriptions of stoneware goods, and, like Messrs. Doulton, have London and country-made pipes. Their productions are invariably of a good sound and impervious nature. There are other firms in various parts of the country who stand equally as high for the excellence of their ware as the foregoing.

Where a drain passes under a house—a method which should be avoided where possible—it is de-

sirable, but not absolutely necessary, to use iron pipes jointed with lead.

A special advantage gained in the use of iron pipes for this purpose is that, being in 9ft. lengths, they only necessitate one joint in a length where stoneware would require four, besides which they are more self-carrying, and not so liable to fracture as stoneware. These pipes should be vertically cast with sockets downwards. They should be truly shaped concentric, and the thickness of metal maintained without variation throughout.

The spigot end of each pipe should be furnished with a projecting bead or fillet, which should fit into the sockets, leaving not more than $\frac{1}{16}$in. clearance all round. Iron pipes for sewage purposes of diameters of 4in., 6in., and 9in., should be 9ft. in length, excluding sockets, and $\frac{3}{8}$in. in thickness for 4in. and 6in. pipes, and $\frac{1}{2}$in. for 9in. pipes. The depth of the sockets should be $2\frac{3}{4}$in., and the weight 160 lb., 236 lb., and 560 lb. each respectively. They should stand a test of between 400ft. and 500ft. of water. The metal used in their manufacture should be free from cinder or inferior iron, and to be strong, tough, and close grained. They should be free from air holes or other imperfections of casting. Iron pipes are sometimes treated with a special process to prevent corrosion from the action of the sewage.

The process known as the Barff is useful for this purpose, and consists of covering the surfaces with a coating of magnetic oxide. It is produced by the action of superheated steam upon the metal when confined in a heated chamber, the coating of oxide being deposited on the surfaces of the pipes by the combustion of the decomposed steam and oxygen. This system has been improved upon to a great extent by a less expensive treatment, known as the Bower process, which is similar to the former, but the magnetic oxide coating is obtained in a quicker and somewhat different manner. Dr. Angus Smith's process, which is another treatment for iron pipes, for the prevention of corrosion, is by heating the pipes to a high temperature and placing them vertically into a heated liquid mixture of coal tar, pitch, resin, and linseed oil, the pipes after immersion being slowly withdrawn and placed in their same upright positions to cool. Before being subjected to this treatment they are well cleaned and freed from any cinder or rust. Having thus given a description of the pipes generally used for house drainage, the next important matter for consideration is the manner of laying them to constitute a clean and effective drain.

Drains should be laid with gradual falls in the same direction from beginning to end. Perfectly straight pipes having been selected, so that they will efficiently drain themselves dry and leave nothing in any hollows to lead to decomposition and foulness, the trench should be excavated a width convenient for working, and the floor finished to the required fall, starting from the sewer end, and should there be any soft place, or where too much has been removed, the filling in should be well consolidated, or concrete substituted for the original material. A length of pipes should be laid in their places with the spigots turned in the direction of the flow of the drain before any joints are made, but in the case of ordinary socket pipes a strand or two of tarred gasket or hemp should be tightly fastened round the end of the spigot of sufficient thickness to firmly hold the same in the socket of the next pipe, but which at the same time must not occupy much of the depth of the socket which is required for cementing. When the pipes are being so laid, small countersinkings or grips should be cut in the trench just deep enough to receive the sockets, in order that the barrels may rest firmly throughout their length on the solid floor of the trench, thus relieving the sockets from undue pressure, probably resulting in the breakage of the pipes and joints for want of uniform support in the direction of their length. It is always necessary where the pipes do not rest on the firm virgin earth to lay a bed of 6in. of Portland cement concrete throughout the length and width of the trench for the drain to rest upon. This can be done before the drain is laid, in which case, when the joints are finished, the space underneath the pipes between the sockets should be well filled up with good fine cement concrete. Sewers and drains up to as recent date as 1845 were as a rule constructed of brickwork, sometimes as circular, and sometimes as square conduits, and the workmanship and materials in connection with them were generally not of the best.

At the introduction of earthenware pipes for sewage purposes, and for some time afterwards the collars or sockets were made by a separate process and placed on them by hand until a method was introduced by which pipes and sockets were manufactured in one piece. For some time the joints were merely made with clay, which very soon washed out. Sound water-tight jointing was not considered of much moment, until its necessity was recognised. At the present time, when nothing but such joints can be permitted, Portland cement for stoneware pipes meets with general approval as an all-round good material sufficient for most cases.

The method of cementing the joints of ordinary socketed stoneware pipes is very important, and is done, in the first place by well caulking the joint underneath, between the socket and spigot, with Portland cement, previously pushing the spigot and gasket well home into the socket.

After the underneath part is filled in, the sides, and lastly the top, should be completed, and at the finish the whole should be trowelled off to a smooth surface. To make sure that any cement which may have gained access to the inside of the pipes is properly removed, a leather disc on the end of a rod, of a loose fit, should be passed through the interior to remove such intruding substance, which otherwise might obstruct the drain.

Worksworth.—At a recent District Council meeting the Medical Officer of Health laid before the members a scheme for building a new reservoir to hold 3,000,000 gallons, which would give a supply for 45 days, the cost being about £4000.

Sleaford.—The Rural District Council at a recent meeting received a letter from the Local Government Board with respect to a proposed loan for a water supply at Scredington, in the Sleaford Rural District. In this case a water diviner had been employed, who made a charge of five guineas, and the Local Government Board had previously refused to allow this amount to be included in a loan, and also £65 expenses in connection with the same. The Board now wrote that it had reconsidered the matter as far as the £65 was concerned, but could not allow the five guineas, the water diviner's fees, to be included.

SANITARY FARM BUILDINGS.

By Louis Hanks, Assoc. San. Inst.

The design and construction of farm buildings is a subject which has from time time engaged the attention and elicited the several opinions of landowners, agriculturists, and architects, with the result that a few model establishments satisfactorily embody both scientific and practical improvements. In other instances the theoretical advantages are admitted, and some limited attempt has been made to carry them into practice (too often with insufficient knowledge or means, and consequently but partial success); but in the majority of cases no attempt has been made to deal with the subject of farm or dairy sanitation.

This is the more to be regretted, as the problem is not in itself a difficult one, nor incapable of effective and economical solution, the evils most commonly met with arising chiefly from ignorance of certain natural laws and consequent neglect of simple but all-important methods and precautions.

It is an ancient but still popular fallacy that matters of sanitation are of less consequence in the case of farms and other isolated country dwellings than in towns and cities where populations are massed in close quarters; the idea being that plenty of fresh air and apparently healthful surroundings will more than neutralise any possible ill effects from dampness of site or structural defects, badly-ventilated apartments, unwholesome water supply, bad drainage, accumulations of filth, and similar dangers too widely prevalent. These erroneous views are sufficiently dangerous to the immediate dwellers amid the evils referred to, but when food products are derived from such a source, as in the case of stock and dairy farm, it becomes a matter of danger to the public health, and as such concerns both the legislator and the sanatarian.

The Dairies, Cowsheds, and Milkshops Orders of the Local Government Board, issued in 1885—86, take cognizance of the dangers to be apprehended from insanitary conditions affecting the milk and dairying industries, and prescribe certain rules and regulations. It is, however, matter for regret that inadequacy of inspection and want of machinery for enforcing these Orders has prevented them being so useful as they might have been.

It is therefore to the enlightenment of those engaged in these businesses that attention should be directed, and the force of public opinion must be exerted in insisting on dairy produce being procured, land vended under sanitary conditions, such as those to be indicated in the course of this paper. This is a matter which is not only of sanitary but of economic and national importance, the failure of profitable arable cultivation over large areas of British land having diverted farming enterprise into the direction of dairy farming and the breeding of live stock for the home markets.

The lesson suggested by these considerations is that farm management must be modified and brought into harmony with recent scientific discoveries, and with improved methods of working as practised in some other countries.

The discovery of the "germ theory of disease" has shed a flood of light on the operating causes or many disorders, whose origin and means of transmission was formerly unknown or obscure. Among other important facts in this connection is the demonstration of the inter-relation of many animal diseases and those affecting man, and of the danger to human health of contracting some communicable disease such as tuberculosis, scarlet fever, diphtheria, &c., by means of meat or milk, particularly the latter.

We have thus two powerful arguments in favour of farm sanitation, the one on economic and patriotic grounds of desire to benefit our own agriculturists by scientific aid in the direction of competing on advantageous terms with the imported produce of foreign rivals, and the vastly important other aspect of the case from the point of view of the public health. In either case the essentials of the subject are the same and may be summarised as a combination of natural forces with artificial aids by the agency of scientific knowledge and common sense. One of the most important points to be kept in mind is the question of expense of improvements. Diminished profits, if not actual loss, and falling returns from the majority of the sources of rural wealth, have so impoverished the exchequers of squire and farmer alike that little or no funds are available in numberless cases for any description of improvement. For this reason the suggestions to be made in these papers will be strictly governed by considerations of the least possible expense.

It is not by any means the most costly scheme which is universally the best or most successful.

Nature, rightly understood, will do so much that little artificial aid is needed.

The chief desiderata of a sanitary homestead are as follows:—A healthy and suitable site, dry, weather-tight, and conveniently-arranged buildings, an ample supply of pure water carefully shielded from chance of pollution, good drainage, so arranged as to promote dryness of site and the avoidance of filthy accumulations in dangerous positions; the use, as far as possible, of impervious and non-absorbent materials for walls, paving, internal fittings, and feeding vessels of those structures devoted to the use of animals, strict attention to the hygienic arrangement and management of the dairy in accordance with modern principles, and in all cases thorough cleanliness, both structural, administrative, and personal. Fresh air and light are, of course, taken for granted, as there should be no possible difficulty in securing these blessings in the case of a farm or any country dwelling.

The first points to be considered are the nature and character of the soil on which the buildings are to be erected, and whether it is effectually drained so as to be perfectly dry, for no advantages in other respects can compensate for a damp situation, both as regards health and property. A house built in a damp situation, even though the greatest care has been taken in making proper foundations, is still unwholesome, and should the materials of which it is built be of a porous or inferior quality, it will be unhealthy as a residence, the structure will decay all the more rapidily, furniture and clothing will become mouldy, and there will be constant discomfort and expense. In low, damp situations, it is well known that the air is at all times charged with a greater degree of moisture than is the case in dry, open positions. A most air suits very few constitutions, either of man or beast, and seldom fails to bring on rheumatism, lung troubles, and other maladies. It also unquestionably favours the growth and development of fungi,

(moulds, &c.), and the bacteria of such diseases as diphtheria, tuberculosis, and malaria.

Damp and water-logged situations are also responsible for much sickness and loss of life among live stock, and consequent pecuniary loss to their owners. Such diseases as bovine tuberculosis (consumption), anthrax, sheep rot, &c., are largely favoured by such conditions, and the expenditure of a few pounds on land draining would often more than repay itself, not only in improved health of the stock, but in benefit grass to land and arable alike.

In any case the immediate site of the homestead should be as dry as it is possible to get it, either by natural or artificial means, and, to avoid the necessity of recapitulation, the remarks on site, soil, and aspect of stables set forth in the first of these articles, which appeared on page 1039 of the *Field* of December 26th, 1896, may be taken as equally applicable to farm buildings where there is any option in the matter, as in the case of a new establishment. In the majority of instances, however, we are met by the difficulty of dealing with old, dirty, or inconvenient erections, which were adapted to the primitive habits and obsolete methods of bygone generations, but which have now to be brought into harmony with the urgent requirements of new conditions.

To achieve this in the cheapest manner it is necessary to keep in mind a few essentials of a modern farming establishment to be guided in any alterations by sanitary rules of construction, making use of such local labour and material as can be obtained at least expense, and to remember that nothing elaborate or architectural is called for in farm buildings where rough-and-ready expedients on proper lines will answer just as well as the most costly or intricate contrivances. Good planning, or the best arrangement of the various structures, yards, and conveniences constituting a homestead, is a matter of considerable importance, not only as regards economy of construction, but even more so with respect to health, comfort, and economy of administration. A badly-arranged house is responsible for much loss of time and temper, as well as for a large amount of unnecessary bodily fatigue; and this, which may be merely an annoyance in a domestic building, becomes a more serious matter in the case of a business establishment, such as a farm homestead of the present day, when success or failure in this industry is a good deal governed by what may appear trifles of small importance.

The loss of a few minutes in traversing a given space may be almost unnoticed in an occasional instance, but when that loss is repeated over and over again in the administration of such an establishment it means loss of money and waste of energy. For this reason the grouping of the buildings should, where possible, be so arranged that the distances to be traversed between the various departments should be as short as possible; that the cow-houses, dairy, beast sheds, piggery, henhouse, and other departments demanding constant administration be disposed in the most convenient position for access in all weathers; and that sheltered communication between the farm house or administrative centre and the departments referred to is advantageous and economical.—*Field.*

LIVERPOOL.—The sanitary arrangements of the Steble-street Baths are to be improved at a cost of £1929.

THE SAFE-GUARDING OF WATER SUPPLIES.

IN the course of a paper read to the members of the Birmingham and Midland branch of the Incorporated Society of Medical Officers of Health on "The Safe-guarding and Examination of Public Water Supplies," Dr. Bostock Hill referred to the recent epidemics at Maidstone, King's Lynn, and other places as having brought prominently to the public mind the danger arising from the pollution of water. These epidemics, he said, had caused the public to become alarmed at a danger which had hardly been thought to exist. Hitherto it was thought that the danger was principally due to private supplies from surface wells, and efforts had been made chiefly to do away with these and substitute for them public supplies supposed to be above suspicion. It was, therefore, hardly surprising that the tracing of the recent outbreaks to the public water supplies had produced something like a shock in the public mind, and called attention to the necessity for special efforts to be taken to safeguard public supplies. Public water supplies were obtained generally from streams, springs, moorland, and deep wells, and these might obviously be polluted from various causes and in different ways. In the case of springs, it was easy to get pollution on the gathering ground or at the point of collection, and it was obvious that it was very important for the gathering ground to be protected from the danger of surface pollution. In the case of deep wells, unless there was negligence, it was not easy at first to see how pollution could occur, providing the water was not originally polluted. Some water engineers at the present day took a stand against well water because its capabilities of minimising pollution were not great. It was, however, more important that the public supply should be above suspicion than that it should have a problematical power of minimising pollution. When a supply was obtained from upland surfaces, it was essential that measures should be taken to see that no source of pollution, particularly human pollution, remained, while animal pollution should be reduced to a minimum, and manuring for agricultural purposes prohibited. The great question of the present time was the fitness of river water for public supplies. Though a Royal Commission had approved of the London supply from the Thames, there was no reason why the conclusion of that body should be regarded as accurate or final. If a river received but a small amount of sewage, there was little doubt but that the purifying powers of nature would render it reasonably safe, if used for a public supply considerably lower down, but he questioned whether that was a condition often found existing. Oxidation, sedimentation, storage, and filtration could be shown to effect a wonderful amount of purification, but methods of purification depending on human effort were known to fail. It was not out of place, also, to consider the matter from the point of view of æsthetics, for nothing more nasty could be conceived than the use for potable purposes of water which was known to have received sewage. He asked whether the time had not arrived when from that point of view alone such water should be discarded as being unfit for drinking purposes. The sewage problem had also to be considered, for sewage effluent could not be abso-

lutely purified, and it was impossible to prevent the effluent gaining access to the rivers. On that ground alone it seemed to him that the supply of large inland communities from rivers must always be open to danger of a grave type. As to the methods for examining water, Dr. Hill insisted that, first of all, the most direct inspection of gathering grounds by competent inspectors was necessary, and that Medical Officers should have the power of entry to all waterworks and gathering grounds. On the subject of analysis there was a tendency, said Dr. Hill, to decry chemical in favour of bacteriological examination. For his own part he enforced the necessity of the use of all means of analysis, chemical, microscopical, and bacteriological, if the examination was to be completely successful.

PUBLIC HEALTH PROGRESS IN THE QUEEN'S REIGN (1837—1897).*

By T. RIDLEY BAILEY, M.D., of Bilston.

(*Continued from page* 14.)

SMALL-POX AND VACCINATION.

The fascinating story of the life of Jenner and the discovery of vaccination has been recently retold in connection with the Jenner centenary, and the report of the Royal Commission has drawn further attention to the subject. On the 14th of May, 1796, Jenner performed his first vaccinations on the human subject, but it was not until 1840 that the first Vaccination Act was passed by which every person could claim to be vaccinated at the public cost. In 1853 the operation was made compulsory on all infants above three months old. Only in 1871 were Boards of Guardians compelled to appoint Public Vaccinators. "Vaccination duly and efficiently performed," says Jenner, "will protect the constitution from subsequent attacks of small-pox as much as the disease itself will. I never expected that it would do more, and it will not, I believe, do less." That vaccination affords protection from small-pox, and that the prevalence of the mortality from the disease has in consequence marvellously decreased, admits of no reasonable doubt. The diminution of small-pox is well stated by Sir R. Thorne-Thorne:—"During the period 1838—42, towards the end of which the advantages of the Act of 1840 were in operation, the rate of mortality from small-pox in England and Wales was 57·2 per 100,000 living, by the end of 1849 it had fallen to 29·7, and during the period 1850—54 to 27·4. It was at this time that the Vaccination Act of 1853 came into operation. The Act embodied the principle of making vaccination compulsory on all infants within a few months of birth—a new departure which had so largely contributed to the prevention of death from a loathsome disease. During the course of the next three quinquennial periods the small-pox rate fell further to 19·8, 19·0, and 14·4 per 100,000 respectively, the latter portion of the last period, viz., that for 1865—9, being in part influenced by the operation of the provisions embodied in the comprehensive Act of 1867." In the epidemic of 1870—72, however, the mortality increased largely, the rate for the five years 1870—74 rising to 42·7 per 100,000, and though this again decreased to 8·3 in the years 1875—79, and to 6·5 for 1880—84, it was obvious that the subject had not been fully understood, and that there were other considerations requiring recognition. It was found that a large proportion of the deaths in the epidemic of 1870—72 occurred in persons over fifteen years of age who had been insufficiently vaccinated in infancy, and as a result of the most careful investigation, it is now known (1) that the lymph to be used must be carefully selected, (2) that the operation must be of a recognised minimum standard, (3) that the protection is frequently limited to a term of years, (4) that consequently re-vaccination is necessary about the period of puberty, and (5) that even when an insufficient vaccination does not give complete immunity it greatly reduces the virulence and fatality of the disease. This is clearly proved by Mr. Marson's experience at the Small-pox Hospital during twenty years. He states that of persons admitted with small-pox—

	Number admitted.	Mortality per cent.
1. Having one vaccine cicatrix ..	2,001	.. 7·73
2. Having two vaccine cicatrices	1,446	.. 4·70
3. Having three vaccine cicatrices	518	.. 1·95
4. Having four or more vaccine cicatrices	544	.. 0·55
5. Stated to have been vaccinated but having no cicatrix.. ...	370	.. 23·57

Again, during the last half of the eighteenth century, small-pox caused 96 out of every 1000 deaths from all causes, and in years when epidemics prevailed this number was sometimes nearly doubled, and now, from the year 1853—the year of compulsory vaccination—to the present time, the proportion is only 10 per 1000. This reduction, however, is confined entirely to very young children, the death-rate in children under five years of age having fallen 80 per cent., while it has actually increased largely in persons over 15 years. Of course, it is easy to understand that compulsory infantile vaccination has prevented the deaths from small-pox of a very large number of children, and has reduced the death-rate from this disease at all ages. After the age of fifteen, when the protecting influence has largely disappeared, unprotected adults form a larger proportion of the community than in the earlier periods when an attack of small-pox was much more frequent.

Not only have the frequency of epidemics, and the severity and fatality of the disease, been much diminished, but the researches of Dr. Collie into the cases treated in the London small-pox hospitals in the two epidemic years, 1871 and 1881, also show clearly (*a*) the larger proportion of severe cases amongst the unvaccinated, and (*b*) the need of re-vaccination about the age of fifteen. Dr. Collie found that, whilst the mortality per cent. of cases is practically identical in the unvaccinated, whether above or below the age of fifteen years, viz., thirty-seven or thirty-eight, the mortality in the vaccinated below fifteen years did not depend so much on the number and character of the scars as it did in persons above that age. Dr. Herbert Goude, Medical Officer of the Highgate Small-pox Hospital, said in 1893, in reference to his institution, where the attendants are all re-vaccinated, "We have now an unbroken record of fifty-eight years, during which no nurse or servant has contracted the disease even in a modified form, and this, too, though the nurses and attendants have on many occasions accidentally inoculated themselves with variolous

* Presidential address to the members of the Midland Branch of the Incorporated Society of Medical Officers of Health, October 7th, 1897.

matter, thus putting the protection afforded by vaccination to a really crucial test. We have had no injurious effects from re-vaccination beyond those apparently inseparable from the operation, such as malaise, and occasionally tardy healing of the vesicles."

The comparative immunity of the vaccinated from attacks of small-pox, and from death, if attacked, has been further confirmed by the experience of the city (Birmingham) in which we are now assembled. Its Medical Officer of Health, Dr. Alfred Hill, in commenting on the small-pox epidemic of 1893—95, after giving various figures in support of his position, sums up as follows:—"The experience of Birmingham, therefore, shows that vaccination confers almost absolute immunity from an attack of small-pox for the first five years, and practical immunity for the first ten years." Furthermore, "It appears that for ten years after its performance, vaccination conferred absolute immunity from death from small-pox, although amongst the unvaccinated of all ages, the disease had a mortality of over 30 per cent.; that is to say, by means of vaccination within ten years from the time of an outbreak, the deaths of 30 per cent. of the persons attacked may be prevented."

In Prussia, vaccination and re-vaccination were made compulsory in 1874, since which time the death-rate from small-pox has been reduced to one-tenth of what it was before (0·24 to ·02 per 1000), and it is stated that in the Prussian army no death from small-pox has occurred since 1874.

It is quite true that, while they admit that small-pox has wonderfully diminished in frequency and severity, the opponents of vaccination assert that this is chiefly, if not entirely, due to isolation and to improved sanitation. This is a point that would have had to be dealt with had it not been for the excellent paper on the subject in *Public Health* by Dr. McVail, who takes his facts from that most admirable book by Dr. James B. Russell, "The Evolution of the Function of Public Health Administration." Dr. McVail, from the history of Glasgow during this century, shows "that the difference in the small-pox death-rate of Glasgow, before and after the introduction of vaccination, simply represented the amount of vaccination practised in the city. Vaccination was a *vera causa*, and the only *vera causa* of the diminution of small-pox." He states what has frequently been proved by others, that "the lesson of greatest interest is, that in spite of insanitary conditions, which are hardly conceivable now-a-days, the Jennerian prophylactic had the same power to protect against small-pox that it has been shown to possess under all other varying circumstances and conditions, even in the case of those whose lives at the present time are spent in the wards of small-pox hospitals, in an atmosphere possibly still more abounding in the poison of the disease than were even the most crowded parts of Glasgow during small-pox epidemics a hundred years ago."

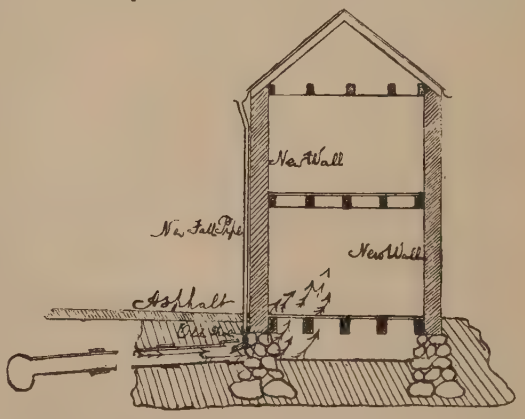
Again, J. C. McVail, M.D., writing on Vaccination and Sanitation, in the *British Medical Journal*, reviewing the progress of vaccination in this and other countries along with the concomitant alterations in the mortality from small-pox, states, "that we can say with confidence what the vaccination law is in any country, from a mere inspection of the small-pox mortality for some years;" and further, that "it cannot possibly be improved sanitation that has caused the remarkable changes in the mean death-rates for more than one reason. Compare Prussia with Austria—there is a sudden and striking change in the death-rate of Prussia in the period succeeding the law of 1874. Now Austria shows no such change in the death-rate, and Austria is still without compulsory vaccination, while Austria has participated in the sanitary improvements of the age. And, on the other hand, Prussia did not suddenly jump into an ideal sanitary condition between 1870 and 1880. But further, the reduction in small-pox mortality has not affected all ages alike, whereas an improved sanitation does affect all ages alike."

In concluding this portion of my subject I need not make more than a passing allusion to the report of the Royal Commission on Vaccination, as it has already been so ably and so frequently discussed in the Press and by the members of this Society. It is satisfactory to note that in the report vaccination is recognised as the preventive of small-pox; that the importance of re-vaccination is insisted upon not later than at the age of twelve years; and that the Commissioners are not prepared to recommend that the State should cease to require vaccination, and trust entirely to a voluntary adoption of the practice. To further this end, and to promote vaccination, it is suggested that every medical man should be a public vaccinator paid by the State, and subject consequently to official inspection in order to prevent abuse, and to procure a minimum standard of efficiency.

A SANITARY DEFECT.

By Wm. Jameson, C.S.I.

The subjoined sketch shows the sanitary condition of a house recently rebuilt in Northallerton. The old walls had been pulled down to just below the floor level, the new walls being built on the old "boulder foundations." The drain communicated directly with the sewer. The new 2in. fall



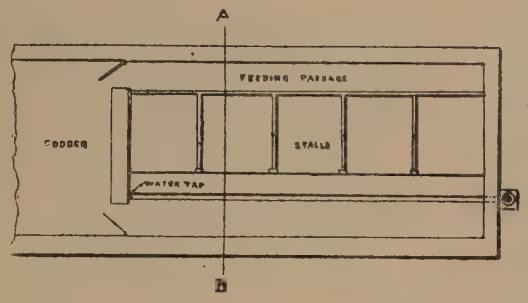
pipe was connected to the old shoe which was never disturbed, and was fixed in the end of the drain, and was completely choked up.

On the occurrence of typhoid fever the drain was examined, when it was found that the sewer gas passed up the drain, through the old foundations, and through the joints in the floor into the house. The yard being covered with asphalt made it almost impossible for any foul gas to escape into the yard. This work was carried out by a "joiner," joiners executing all the "plumbers' work."

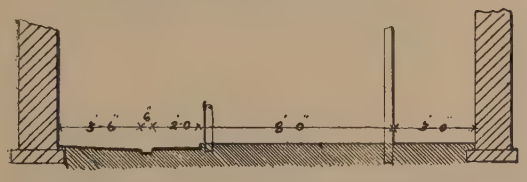
THE SANITATION OF COWSHEDS, DAIRIES, AND MILKSHOPS.

By Dr. JAMES R. KAYE, Medical Officer, West Riding of Yorkshire.

THE importance of dairies, cowsheds, and milkshops in connection with the public health becomes every year more apparent, and consumers are gradually awakening to the dangers lurking in contaminated milk. No fewer than sixty-nine outbreaks of epidemic disease in this country have been distinctly traced to milk, and it has been demonstrated that the tubercle of man and bovines is intercommunicable. Milk is one of those articles of food which, if exposed to foul gases, the effluvia of decaying matter or to infection from persons, is readily contaminated, and it acts as an excellent nidus for the multiplication of the poison absorbed. Still, the impression gathered from an analysis of the reports of the local Medical Officers of Health is that there is a decided apathy and indifference



Enlarged Section on A.B



amongst Local Authorities in the enforcement of the regulations for the proper management of dairies, cowsheds, and milkshops. The Order of 1885 is intended to secure the registration of all premises where milk is sold, and it is the duty of the Sanitary Authority to make regulations for the inspection of cattle, and for prescribing and regulating the lighting, ventilation, cleansing, drainage, and water supply, for cleaning and maintaining cleanliness and every care against infection or contamination of the milk.

In many districts no regulations have been framed, and others have regulations but do not enforce them beyond, perhaps, whitewashing—hence the Order has been dubbed the "Whitewashing Order." In few reports is there any detail beyond a general statement that they have been inspected and found satisfactory or otherwise. It may be that structural difficulties seem to overawe the officials; still, drainage, so frequently in a bad condition, might easily be remedied, light could be provided or increased, and cleanliness insisted upon. There are, indeed, sufficient grounds to vigorously tackle these premises for the protection of public health, and also on behalf of the dairy farmers and milk purveyors themselves.

The official undertaking this work should be prepared with a sketch—somewhat after the fashion of the one annexed — to overcome the argument, so often advanced, that "it is easier said than done."

The floor should be made of concrete or flags set in cement. Some prefer the stalls to be clay floored. The dimensions indicated above are those generally adopted in good designs. In existing buildings, where space is limited, the feeding passage might be curtailed or left out, but it should be present in all new buildings.

There should be little difficulty with whitewashing and the renovation of the floors, and in the admission of light, or provision of proper water supply. These are essentials which ought always to be *enforced*. Some difficulty comes with ventilation, and in giving advice one should be careful to indicate means which will not cause cold air to pass directly on to the cows. The gratings, say 27in. by 9in. for every two cows, should be placed under the eaves, and a louvre should, if possible, be erected on the ridge. Until decisive action is taken it will be impossible to report satisfactorily on these premises.

One word regarding the tuberculin test for tuberculosis in cattle. This is a simple test which experience proves has yielded highly satisfactory results, though it is not altogether infallible. In many of the American States the Authorities carry out a regular system of examining all cattle and testing them by tuberculin. It is a liquid obtained by the concentration of glycerinised bouillon in which the germs of tuberculosis have been grown. In sound cows its injection has no effect, but in a tuberculous animal it produces symptoms indicative of the disease, so that in tuberculin we have a means not only of ascertaining the soundness of the animals yielding the milk supply or about to be used as food, but an agent whereby stockbreeders and farmers may largely eradicate tuberculosis from their animals.

Mr. Greenwood, of Ossett, writes: "This disease (tuberculosis) is known to be very common in the cow, and may undoubtedly be transmitted to the human species through the milk of tuberculous animals. The character of the cow disease which renders the milk dangerous has yet to be determined, though it has been ascertained that when the udder is affected the danger is undoubted."

ANOTHER L.G.B. ORDER ON WATER SUPPLIES.

THE Maidstone epidemic has certainly had the effect of "waking up" the officials at headquarters, and circulars to the various Councils are following each other in quick succession. In the one issued this week reference is made to the recurring tendency to sudden localised epidemics, in which the typhoid infection is distributed to large populations by means of the contamination of water, it points out that the Council is the body responsible under the Public Health Acts for securing to the inhabitants of their district a proper and sufficient supply of water, desires to impress upon them the importance of taking the matter into their serious consideration with the object of guarding their district against dangers the gravity of which has

been sufficiently shown by recent examples. Where the Council have themselves constructed or purchased any waterworks it is their duty in pursuance of Section 55 of the Public Health Act, 1875, to provide a supply of "pure and wholesome" water, and in order to fulfil this obligation it behoves them to exercise every precaution to secure that the water which they deliver to the consumers shall be protected from risk of contamination; and where means of filtration are necessary these should be adequate and maintained in a thoroughly efficient condition. Not only are the Council thus under a responsibility for the wholesomeness of the water which they themselves supply, but they should by careful inquiry make themselves acquainted with the sources, nature, and quality of the various supplies in all parts of their district, and should take all such steps as may be within their powers with the view of supplementing or improving the supplies.

The Board observe generally that accurate information should be procured in such matters as the following:—(1) Whether water is derived from gathering grounds or from springs; whether drainage from human habitations, farmyards, and the like, finds its way directly or indirectly into the reservoir or to any part of the water service; and whether risk of access to the water of human excreta and similar refuse is likely to arise. (2) Where water is derived from deep wells; whether surface or other water, liable to be contaminated by drains, sewers, cesspools, and the like, reaches or is liable to reach the wells; the existence and direction of fissures in the strata deserve special consideration in this respect. (3) Where water is derived from shallow wells; whether the wells are so circumstanced that they run risk of contamination by reason of drains, cesspools or middens, or by the deposit of manure in or on the ground in the neighbourhood of the wells.

IS CIGARETTE SMOKING INJURIOUS?

It is a popular delusion that when the smoke of a cigarette is inhaled it pervades the air vesicles of the lungs, and the nicotine it contains is all absorbed into the blood through the delicate respiratory membrane. As a matter of fact, the smoke reaches only to the larger bronchial tubes, probably in a majority of instances not to a point much below the larynx. To the mucous membrane of these large air passages the smoke does little harm as an irritant, although it may aggravate pathological conditions already present. The surface by which nicotine is absorbed into the blood is much larger than that of the mouth, however; so that, although relatively only a little of the poison is contained in a cigarette, much more of it finds its way into the system than when the smoke from a cigar or pipe is simply drawn into the mouth and at once blown out. The inference to be drawn from this is that the inhalation of tobacco smoke is a bad practice. That it is more likely to be indulged in by persons who smoke cigarettes than by those who restrict themselves to cigars and the pipe may be readily conceded. At the same time it is quite certain that many smokers inhale cigar smoke and pipe smoke at times, if not habitually; sometimes they do it involuntarily. Equally absurd is the common assumption that cigarettes are especially injurious on account of their containing other poisons besides nicotine. Ledaux, who has subjected various brands of cigarettes to chemical analysis, found absolutely no evidence of any other drug but nicotine in the tobacco, and in the paper a harmless quantity of cellulose. It is, indeed, the height of absurdity to suppose that cigarettes are sophisticated with opium. Opium, as has been often said, is too expensive to be used for such a purpose. The chief evil of tobacco is its constitutional effect upon the nervous system, and as the cigarette habit is so common in boys, it is to be deplored on that account.

Sanitary Inspectors' Associations.

THE NORTH-WESTERN AND MIDLAND.

The tenth meeting for the current session of the above Association was held at the Royal Institution, Colquitt-street, Liverpool, on Saturday, January 8th, 1898. There was a good attendance of members, including representatives from Liverpool, Manchester, Crewe, Rhyl, Wallasey, Ashton-in-Makerfield, Astley Bridge, St. Helen's, Lymm, Waterloo, &c., the president (Dr. Vacher) occupying the chair.

The formal business having been transacted, Messrs. A. H. Fidoe, W. Vale, J. Ablett, and P. V. Rigbey, district Sanitary Inspectors, Birmingham, and W. J. Bruford, district Sanitary Inspector, Manchester, were elected as members, the Council's nomination of Mr. A. D. Greatorex, Borough Engineer, West Bromwich, as an honorary member, being also approved. Some additional nominations having been received, the chairman called upon Dr. James Niven, M.A., M.B., Medical Officer of Health, Manchester, to deliver an address on :—"Public Administration Procedure in connection with Infectious Diseases."

The lecture, which was of a highly interesting character, dealt largely with the methods employed by the Public Health Department of Manchester, complete sets of the various forms, &c., in use in that city being distributed to the members for reference. Cases of infectious disease were notified to the Medical Officer under the Manchester Provisional Order of 1881, the medical attendant stating on the certificate the name, age, and address of the patient, and also giving the name of occupier, or other person having the charge or control of the building or room, the nature of the disease, the medical attendant being also requested to state as to whether or not the patient was fit for removal to the hospital. Where the Sanitary Inspector had reason to suspect the existence of infectious disease, it was the custom for the Medical Officer of Health to request a medical man to visit and report on the case. Under this dual system there was less danger of cases escaping notification. The next point to be discussed was the formal report on the case, this duty devolving on the Sanitary Inspectors, the amount of work done in this respect being most remarkable. Tact and method were the two prerequisites to a successful report, the last named being best secured by a careful attention to the printed requirements of a form which was specially devised for different diseases, according to the special facts which required to be elicited. In the case of enteric fever inquiries were instituted into

the subjects of the drinking water, milk supply, shell fish, ice cream, and food supply generally. From the reports so supplied much valuable information had been extracted, and some interesting relations between soil pollution and infectious disease had been made apparent.

Immediate information of outbreaks of infectious disease amongst children attending schools was transmitted to the head teachers, and in case of several cases occurring at the same school, a special circular was despatched with a view to securing the aid of the teachers in the investigation of cases which had been overlooked. A list of cases of infectious disease notified was also daily transmitted to the School Board offices, similar intimations being given when disinfection had been satisfactorily carried out. Notice was given to the chief librarian when it was believed that infected persons had been handling books borrowed from the Public Free Libraries. The question of isolation received the utmost attention, and the proportion of patients suffering from scarlet fever removed to hospital was unusually large. Their hospitals appeared to be well appreciated. Although measles and whooping-cough were not notifiable diseases in Manchester special precautions were taken to prevent the spreading thereof. The school attendance officer left handbills at houses where school children were stated to be suffering from measles directing the parents to refrain from sending children to school until four weeks should have elapsed from the commencement of the last case of measles or whooping-cough as the case might be ; and where cases came under the cognisance of the Health Department, notices were sent to the teachers.

The sanitary officers made a brief report when these diseases resulted fatally, and in consequence of such inquiries, and also by receiving reports from the school attendance officers it was possible to ascertain if a considerable number of cases were associated with any one particular school, in which event closure followed ; the closing of the Infants' Sunday-school, if there was one held on the same premises, being also suggested.

As regarded disinfection, it was their custom to wash the floors, walls, and ceiling with a solution of chlorinated lime, the bedding and clothing being removed and subjected to the action of moist steam. Chlorine gas was evolved in the infected rooms, but no very great importance was attached to aërial disinfection.

Dr. Niven then went on to explain the methods adopted for the prevention of diarrhœa, dysentery, and consumption, pointing out the great necessity that existed for educational work in this direction. Where fatal cases of these diseases were reported, special reports on the subject were made by the Sanitary Inspector, and every facility as regarded disinfection was offered in the case of consumption.

A final branch of their work, and one to which he (Dr. Niven) attached great importance, was the special facilities which the Manchester Corporation offered to medical men in the diagnosis of suspected cases of diphtheria and typhoid fever. The Corporation had secured the services of Prof. Delépine, of Owens College, for the purpose of undertaking a bacteriological examination of the material obtained from cases suspected to be suffering from these diseases at the request of the practitioner in attendance, and it was most satisfactory to be able to state that in the majority of cases medical practitioners did avail themselves of the opportunities so afforded.

At the close of his address, Dr. Niven gave a practical illustration of the working of the portable steam disinfector invented by Professor Delépine.

The CHAIRMAN opened the discussion, which was rendered brief owing to the lateness of the hour, and was followed by Mr. WM. URQUHART (Crewe) and R. JOHN HUGHES (Rhyl), a hearty vote of thanks being accorded to Dr. Niven. The lecturer's reply brought to a close a most enjoyable and instructive meeting.

ANNUAL REPORTS.

IN the matter of conciseness we commend the following report presented by Dr. T. Haworth, Medical Officer of Health, to the Filey Urban District Council :—"In presenting my report for the year 1897, I have to inform you that the total number of deaths for the year is 54, which gives a a death-rate of 20·7 for the year. This includes the deaths of three visitors, one being a baby, who was accidentally burned to death, the remaining two being elderly people who were more or less invalided, with a tendency to apoplexy, and who succumbed to an attack whilst visiting Filey. By excepting the three visitors named, the death-rate in the residential population of Filey would be 19·6, a slightly lower death-rate than that for 1896. The deaths in the last quarter were six, giving a death-rate for the quarter of only 2·3, which I believe to be one of the lowest death-rates for a single quarter in Great Britain. Considering that during the year we were visited by an epidemic of scarlet fever, which caused the death of six children, I think we may congratulate ourselves that our death-rate is so satisfactory, after passing through this general epidemic. Looking at the deaths for the year, I find that 16 persons passed the age of 65, there being 37 males and 45 females. The number of births in the year was 82, two more than the number for 1895, giving a birth-rate of 31·5 per 1000. There has been only one case of scarlet fever reported in the quarter, and I think that the Council may look upon the epidemic now as being quite stamped out. There were a few cases of measles in November, but I have heard of no further cases during the last month. I think it would be well for the Council to include measles in their notification list. I believe that during the year we have been quite free from typhoid fever, which speaks well for our drainage and water systems. I have heard few complaints of nuisance, and I consider the removal of refuse matter has been carried out most admirably. I am very pleased that the Notification and Prevention Acts have been adopted, and are now in force, and I hear that the Board are continuing their efforts for a small isolation cottage, with the necessary disinfecting apparatus. There is no need to build a costly one for a town of the size of Filey, but a small and efficient one is absolutely necessary if we are to protect ourselves against zymotic diseases. The Sanitary Inspector and myself have made

monthly visits to the schools which were closed, to the bakeries, workshops, and slaughter-houses, and have examined the milk cans, and have found them all in a satisfactory condition."

INSANITARY BARBERS' SHOPS.

In these days of antisepsis it seems rather strange the barber shop has not attracted more attention than it has. There is probably no medium better for conveying infection than soap lather; and yet in the average barber shop hundreds of people are lathered from the same cup, in which more or less infective material is apt to remain.

Recently a barber was summoned before the police-court for operating in his shop while himself suffering from an infectious disease—diphtheria. Notification had been received from the medical man in attendance, and the barber warned, but nevertheless he continued to ply his calling, and the evidence went to show that at least one case of diphtheria was communicated through him.

It would seem, considering the dangers that threaten, power ought to be conveyed to Sanitary Inspectors to inspect barbers' shops, their paraphernalia, &c., and direct how the management of the same shall be carried on.

The fact that barbers' razors are dipped so often into hot water probably accounts for the fact that so few cases of infection are reported from this source.

Reviews.

House Drainage Manual. A Guide to the Design and Construction of Systems of Drainage and Sewage Disposal from Houses. By Wm. Spinks, Assoc. M. Inst. C.E. With tables, illustrations, extracts from the Public Health Acts, Metropolis Management Acts, and model bye-laws relating to house drainage. Price 5s. Biggs and Co. 306 pp.

We are pleased to welcome the publication of this book, not because there was a dearth of books on house drainage, but because there was no good book published dealing with the practical side—as this book does—of the designing and construction of underground drains. This book is just the one which can be safely put into the hands of Sanitary Officers who are entrusted with the superintendence and construction of house drainage, external to the house. There is no attempt to deal with the plumbers' work as appertaining to house drainage, and we think this is wise, as the treatment of the subject requires a volume in itself, such as that of Mr. S. S. Hellyers' "Plumber and Sanitary Houses."

The first nine chapters of the book comprise the following subjects, viz., "Sanitary Surveys," "Defective Drainage," "Requirements of Houses," "Planning and Arrangement of Drains," "Subsoil Drainage," "Inclination of House Drains," "Pipes and Jointing," "Ventilation of Drains," "Intercepting Traps," while Chapter X. is devoted to "The Setting-out and Construction of Drains." This chapter describes very fully how to take levels and prepare the working section, the method of laying pipes to the gradient by the sight rail and boning-rod, excavating and timbering of trenches, connection to sewer, hydraulic testing for soundness of joints, and how trenches should be refilled.

Subsequent chapters deal with cellar drainage, the construction of manholes and lampholes, the disconnection of waste pipes and gully traps, different forms of traps, the flushing and cleansing of drains, and the necessary apparatus for the purpose, such as syphons, tippers, &c.

There is also a valuable chapter on the disposal of sewage from isolated houses, and a description, with illustrations, of land purification, chemical precipitation, and the varying forms of tanks used for the purpose, including the Candy tank and the Dortmünd tank. The Natural Purification Company's (Nottingham) process, the International Company's, and the Magnetite Company's processes of sewage purification are also described, while the latest developments of sewage purification, *i.e*, on biological principles, as carried out at Exeter by the septic tank and at Sutton by the bacteria tank, are fully stated. Illustrations are also given of the mode of construction of bacteria tanks and filters, as well as details of the method of working, the author stating that he has "several times visited the filters at Sutton, and so far as relates to the clearness of the effluent, the absence of all smell both from it and the filters, I can personally testify as well as to the disappearance of the sludge."

The concluding chapters treat of legislation relating to house drainage under the Metropolis Management Acts and under the Public Health Acts. The book, as we have already indicated, will be found most useful to all persons whose duty it is to design or superintend the drainage of houses, and with the details given as to the construction of sewage filters and various forms of tanks, it will be especially valuable if used in conjunction with the same author's book on "The Drainage of Villages," to those who have to prepare schemes for the sewerage and sewage disposal of villages. The book is well written and clearly printed, and may be safely recommended to architects, surveyors, and inspectors.

Obituary.

MR. ERNEST HART.

We regret to announce the death of Mr. Ernest Hart, editor of the *British Medical Journal*, and for many years editor of this journal, which took place at an early hour on Friday morning at Brighton, where he had been staying for some months for the benefit of his health. Early in September Mr. Hart, who had for many years suffered from diabetes, underwent amputation of the leg. The operation, which was performed by Mr. Lockwood, was successful, and led to such an improvement in Mr. Hart's health that at first there seemed to be every prospect of his returning to active work at no distant date. Mr. Hart was born in London in 1836, and received his early education at the City of London School, of which he ultimately became captain and Lambert Jones Scholar. Having chosen medicine as a profession, he entered at St. George's Hospital, where he had a distinguished career as a student. He became a member of the Royal College of Surgeons of England in 1856, and taking up eye diseases as a speciality, he acquired an extensive consulting

practice in the City. At the age of twenty-eight he was appointed ophthalmic surgeon at St. Mary's Hospital, becoming later Dean of the Medical School. He published various papers in the "Transactions" of the Royal Medical and Chirurgical Society, and in the Moorfields Ophthalmic Hospital reports, and introduced into ophthalmic practice some modifications which have since been widely adopted. Nor did he confine his attention to diseases of the eye. His name is associated with a method of treating popliteal aneurism, which he was the first to use in this country.

Mr. Hart's real life-work, however, was done in the field of journalism. At the age of twenty-two he became a member of the staff of the *Lancet*, at that time under the vigorous editorship of its founder, Thomas Wakley. He took a leading part in the exposures which led to the appointment of a commission of inquiry into the state of the London workhouse infirmaries, and ultimately to the establishment of the Metropolitan Asylums Board, and to a thorough reform of the treatment of the sick poor in workhouses throughout the country. Another campaign which owes its success in large measure to Mr. Hart is that against baby farming, the issue of which was the Infant Life Protection Act. In 1866 Mr. Hart was appointed by the council of the British Medical Association to the editorship of the *British Medical Journal*—a position which he continued to hold till his death. He was till recently chairman of the Parliamentary Bills Committee of the British Medical Association, and was also for many years chairman of the National Health Society. The record of his public work covers nearly the whole field of sanitary legislation during the last thirty years. In the amendments of the Public Health and of the Medical Acts; in the measures relating to the notification of infectious disease, to vaccination, to the registration of plumbers; in the improvement of factory legislation; in the remedy of legitimate grievances of Medical Officers of the Army and Navy; in the removal of abuses and deficiencies in the management of barrack schools, and in the promotion of many other reforms, Mr. Hart worked strenuously and successfully. In 1894 he visited India, and at the Sanitary Congress held in Calcutta he denounced the sanitary backslidings of the Indian Government, particularly in regard to the prevention of cholera.

In addition to innumerable editorial articles in the *British Medical Journal*, Mr. Hart wrote occasionally in the *Nineteenth Century*, the *Century*, the *Forum*, in this, and in other periodicals. He contributed chapters on cholera and on vaccination to the great "System of Medicine" now in course of publication under the editorship of Professor Clifford Allbutt; and a chapter on waterborne diseases to the "Twentieth Century Practice of Medicine." He was the author of reports on the influence of milk in spreading zymotic disease, on vaccination, waterborne typhoid, &c., which have been recognised as of great value by Medical Officers of Health and epidemiological authorities. He wrote also on the ancient arts and artists of Japan, a subject on which he had qualified himself to speak by a visit to Japan, and by the formation and study of one of the best collections of specimens of Japanese art in Europe. In 1893 Mr. Hart received the honorary degree of D.C.L. from the University of Durham, and it is understood that a similar honour would have been conferred upon him by the M'Gill University had he been able to attend the annual meeting of the British Medical Association held last August at Montreal.

Mr. Hart married a daughter of Mr. Alexander Rowland, of Lewisham, a lady who is herself well known as an accomplished writer and a philanthropic worker. He leaves no issue.

General News.

BIRMINGHAM.—The Sanitary Institute is to be invited by the City Council to hold its 1898 Congress in this city in September.

RUGBY.—It has been decided to build additional slaughter-houses, and, when needed, to endeavour to purchase land in the vicinity for extending the market.

BEDWORTH.—A public meeting is announced for the purpose of considering the proposal of a London firm to supply Bedworth and adjoining districts with water.

NEW MILLS.—The Urban District Council, upon the advice of the engineer, Mr. Bancroft, has decided to advertise for meters for the Ollersell Waterworks, and to divert the road near the Workhouse.

EAST DEREHAM.—At a recent meeting of the Urban District Council a lengthy report was submitted by the Sanitary Committee with regard to the sanitary condition of the town, and a resolution was passed directing further facilities for cleansing the town.

BEDALE.—The Rural District Council has decided that steps be taken to carry out the water supply scheme submitted by Messrs. Fairbank and Son, of York, and that it be sent to the Local Government Board for approval. It was stated that a water supply could be obtained from Spring Wood at a cost of £2850.

LUDLOW.—A special meeting of the Town Council was held recently to receive a report from the Sanitary Committee as to prohibiting the sale of milk in the borough from a certain dairy in consequence of an outbreak of typhoid fever, and to make whatever orders on the whole question might be deemed advisable.

GOOLE.—The Urban District Council has sent a deputation to consult Mr. de Rance, of Manchester, with a view to steps being taken to improve the present water supply or to obtain a new one. It has also been decided to appoint a gas and water manager, at a salary of £300 a year, instead of continuing the dual control by sub-managers and a consulting engineer.

LLANELLY.—A peculiar type of measles is raging in Llanelly, hundreds of cases being now under treatment. So serious has the outbreak become that several of the largest Board Schools in the town have been closed. The doctors describe the epidemic as one of German measles, the symptoms differing from those usually present in ordinary cases of measles. The visitation is especially present in the Lakefield and Greenfield districts, almost every house where there are children being affected.

PICKERING.—The Medical Officer reports that influenza of a very bad type is sweeping over the district.

CHISWICK.—The District Council has entered into an agreement for the purchase of a site in the Brentford district for the erection of an isolation hospital.

PEMBROKE DOCK. — The Local Government Board has sanctioned the scheme for supplying Pembroke Dock with water from the Milton springs, at a cost of £27,000.

TOWCESTER.—With regard to Eastcote water supply, Mr. J. Eunson (the engineer) reports that he estimates the cost of the scheme will be £350, exclusive of land or rights.

BO'NESS.—Mr. Thomas Beattie, Bo'ness, has secured the contract for the construction of a new storage reservoir at Lochcote and other works in connection with the new water supply for Bo'ness.

CHESHIRE.—A memorial has been adopted to the County Council of Cheshire asking that body to establish a county laboratory for the chemical and bacteriological examination of water, milk, &c., for the county.

LANGTON MALTAVERS.—A Local Government Board inquiry has been held into an application from the Rural District Council to borrow £1000 to sink a well and construct a reservoir and pipes to supply the parish with water.

ROWLEY REGIS.—Mr. Fiddian, of Stourbridge, has been instructed by the Urban District Council to prepare the scheme for the improvement of the insanitary area known as Tibbett's Gardens, both as to street-making, drainage, water supply, and gas.

NOTTINGHAM.—The second reading of a report relating to the reconstruction of a portion of the Leen Valley sewer and other works connected therewith has been agreed to, and also the construction of an underground lavatory at a cost of £1500.

WEST BROMWICH. — In consequeuce of the recent outbreak of typhoid fever at Maidstone, the Sanitary Committee of the Town Council has had the South Staffordshire Waterworks Company's water analysed, and the results are eminently satisfactory.

MARKET BOSWORTH. — The Rural District Council has decided to erect an isolation hospital at Ibstock on account of an alarming outbreak of scarlet fever. Ibstock has a population of 3000 to 4000. Scarlet fever was first reported on September 15th, and there are now fifty-three cases.

STAFFORD. — A Local Government Board inquiry has been held with respect to an application by the Town Council for sanction to borrow £4000 for purposes of water supply, and £20,000 for the purposes of the Stafford Corporation Act, 1896. In view of the general adoption of the water-carriage system of sewerage, the Corporation decided to increase the water supply by erecting additional machinery, &c., and under the Act of 1896, it has power to convert existing pan-closets into water or slop-closets in those cases where owners of property had complied with the wishes of the Town Council, and had abolished the vault-closet system for the Rochdale tub system.

Sewerage Schemes.

[TO MUNICIPAL ENGINEERS AND SURVEYORS.—The Editor will be pleased to receive items for publication relating to sewerage schemes projected or inaugurated, together with explanatory diagrams or photographs. The former should be drawn and lettered in black ink.]

THE Local Government Board has sanctioned the borrowing by the New Mills Urban District Council of £6532, for sewerage purposes.

THE sanction of the Local Government Board to a further loan of £984 for the drainage of Aston Fields has been received by the Bromsgrove Council.

MR. DIBDIN, late chemist to the L.C.C., has been asked upon what terms he will advise the Shipley Council as to the treatment of the sewage of the district.

THE Rural District Council of Wirral has decided to apply to the Local Government Board for permission to borrow £300 to lay down experimental Dibdin's filtration tanks to improve the sewerage system at Prenton.

A LOCAL Government Board inquiry has been held at Teignmouth concerning the District Council's application for leave to borrow £640 for works of sewage disposal, and for the erection of a mortuary and disinfecting chamber.

THE scheme of the engineer for the drainage of Cefn Bychan and Newbridge, at a cost of about £2000, has been submitted to the Wrexham Rural District Council. Negotiations are to be opened up for the outfall and the sewer easements.

THE Haywards Heath Urban District Council has requested Mr. Dibdin to advise it as to the construction of the necessary tanks for sewage disposal, to prepare plans, supervise the works, make necessary analyses, and put the process in working order.

A COMBINED scheme for improving the outfall of the sewers of the town of Calcutta proper, and for draining the suburbs and the area between the canal and the Circular-road, was commenced during last year. Larger pumps are to be fixed at Palmer's Bridge, a new high-level sewer is to be constructed which will meet a high-level sewer intended for the suburban outfall, and the combined sewage of the town and suburbs is to be carried in a channel lined with masonry to a new outfall at Baintolla, some miles below the present outfall in the Balliaghata Canal. A main sewer is also to be constructed which will enter from Watgunge on the Hooghly bank, and passing under Tolly's Nala by gravitation, will discharge at a station to be established near the rifle range on the Eastern Bengal State Railway. The suburban outfall will be precisely similar to that now working at Palmer's Bridge. There will be two pumping stations for the suburban main sewer, one at Budge-Budge-road, and one at the outfall. The temporary project for the suburban drainage has been carried out.

THE Urban District Council of Staines is taking steps to obtain a further loan of £3500 on drainage account.

A LOCAL Government Board inquiry has been held at Manchester into the application of the Corporation to borrow £180,000—£170,000 for the purposes of sewerage and sewage disposal and £10,000 for market purposes. There was no opposition to the application.

A LOCAL Government Board inquiry has been held at Somerset into the application of the County Council for consent to take proceedings under part three of the River Pollution Prevention Act, 1896, against Messrs. Coombs and Co., of the Clandown and Radstock Breweries and Hotels Co. Ltd., in respect to the alleged pollution of the river Somer.

IT is proposed by the Epsom Rural District Council to construct certain works on land on Roxley Farm, which is within the district of the Surbiton District Council, for receiving and distributing the effluent water from the sewage tanks, and enabling it to be treated on the land in question by means of irrigation or filtration, with an outlet for the final discharge of the water into the Hogg's Mill river. The Epsom Council give three months' notice of their intention to construct the works in question.

AT a recent meeting of the Hampton Wick District Council the Drainage Committee reported that they had directed the clerk to send to the gas company for their observations a copy of the letter from the Native Guano Company, on the subject of the alleged gas refuse in the sewage delivered at Kingston. A reply from the gas company was read, in which it was stated that no deleterious matter was, or ever had been, discharged into the Council's sewers, and the charge referred to was incorrect so far as this company was concerned. The letter was referred to the Drainage Committee to enable them to make independent inquiry.

AT a recent meeting of the Sunbury District Council, a report was read from Mr. Dibdin upon the question of treating sewage by bacteria. This was the outcome of a visit Mr. Dibdin made to Sunbury. He stated what would be required, the tank capacity, &c., in respect to the single treatment followed by land (with the use of coarse beds only), and the double treatment (with coarse and fine beds); but he did not advise the Council what to do in the matter, or as to the probable cost. Mr. Anstie explained that the cost of the single treatment, as proposed by Mr. Dibdin, would be £1528, including all charges. With regard to the double treatment, he disagreed with Mr. Dibdin in one or two details. He would advise that the coarse beds remain the same as in the first system, and that the fine beds be separate. That would cost altogether about £2800. The saving in chemicals and sludge would be about £80 a year. Finally, it was decided to apply to the Local Government Board, asking it to allow the Council to adopt the bacteria system with the coarse beds only.

THE Irvine Town Council has decided to approach the Local Government Board asking an opinion on the scheme for conveying the drainage by means of pipes beyond the weir.

THE drainage of St. Helen's, Crawford Lodge, Ashcliff, and Binrock requiring to be carried out beyond the filling up of the Esplanade ground in front, the Burgh Engineer for Dundee has been instructed to see to the work being done. The estimated cost is about £100.

WITH reference to the improvements to be carried out in the sewerage system at Portrush, the cost has been estimated at £300, but the whole work could be carried out for £50 if the flushing tank, which would cost £50, was omitted. The Town Commissioners have decided that the improvements be carried out upon this understanding.

AT the last meeting of the Gomersal District Council, two letters were read from the Rivers Board with reference to the drainage of Great Gomersal, the latter of which intimated that the Board would now be satisfied if it was kept informed from time to time of the progress of the scheme. Later on plans and sections of the scheme, with a detailed report and estimate of cost, were laid before the Council by a representative of Mr. J. Waugh, engineer, Bradford. The estimated cost is £7577.

A START has just been made with the new main sewer system adopted by the Douglas Town Council, after debates and opposition extending over years, the last opposition of a month ago having led to the withdrawal of the tender of a Glasgow firm for carrying out the land section of the work at a cost of £26,000. The revised estimated cost, excluding any rise that may result from the withdrawal of the main tender, is £50,000. The section of the work just started is the new outfall, which will give a new discharge point for the sewer in the deep sea, about a quarter of a mile to the north-east of Conister, where there is nine hours' ebb tide, which will carry the sewage clear of the bay.

MR. ED. COUSINS, civil engineer, London, has forwarded to the Penybont Main Joint Sewerage Board his report on the best system of dealing with the sewage of the district, basing his estimates on a fifteen years' increase in population to bring it up to 20,000. He decided against an open outfall for sewage into the sea at low-water mark, and submitted two estimates for the Board to consider. These were:—(1) For the sea outfall, the sewers having self-cleansing gradients and a brick tank sewer for containing the sewage at times when the outfall sewer is tidal locked, including penstock, tidal valves, &c., £13,642; (2) for the septic tank scheme, with filter beds on the sand banks and effluent drains into the river, capable of dealing with a population of 20,000—£18,799. The Board has unanimously decided not to take the storm water from the Bridgend and Penybont areas into the scheme, as that would cost an additional £7000, and has resolved that Mr. Cousins be invited to a conference with the Board on the scheme prepared by him.

AT a recent meeting of the Sewerage Committee of the Aberdeen Town Council a report from the Sanitary Inspector with regard to the condition of the sewage at Kepplestone was remitted to the Burgh Surveyor for further report. It was agreed to carry out an extension of a sewer in Craig-place, Menzies-road, at an estimated cost of £58. The following tenders for the extension of sewers were accepted:—Brighton-place, Mr. Roderick M'Kay, £20 10s. 9d.; Bayview-road, Mr. John Bain, £85 17s. 2d.; Dunbar-street, Mr. A. M'Kay, £85 12s. 11d. The tenders of Mr. John Hector for supplies of fire-clay pipes and syphons, being the lowest offers, were accepted.

FOR some considerable time past the question of the drainage and sewerage of Castle Donington has engrossed the attention of the Local Authorities. The Local Government Board has plainly intimated that by some means or other a better system of drainage must be adopted as early as possible. The authorities have at length decided to inaugurate a system of sewerage and drainage on approved scientific principles, viz., precipitation with irrigation. A deputation was sent by the Parochial Committee to Kimberly and Tibshelf, where this principle is already in operation, and they were well satisfied with what they saw. The workings were in splendid order, despite the fact that the day of their visit was not one of the most favourable for their purpose. The result is that the responsible authorities will proceed to the adoption of a similar scheme for the disposal of the sewage of Castle Donington. The scheme is estimated to involve an outlay of £6500, which amount includes the cost of a duplicate engine and other appliances ; but as it is thought that several of these items are non-essential, it is expected that the estimate will prove to be considerably above the actual cost.

THE Town Council of the metropolis of Natal seems to have definitely decided upon introducing the water-borne sewage system into that town, the consequence of which will be a great demand on home firms for the necessary sanitary appliances, house fittings, &c. As it is impossible to get the natives to properly use the ordinary conveniences, special latrines will have to be supplied for their accommodation, and in catering for these it would be well for home firms to send experts to ascertain the special requirements of the situation. The new installation will involve an increase of the water supply to the town, which will be drawn from the Umsindusi, either above the Edendale Falls or at Fort Napier, in the former case involving the acquisition of heavy steam pumping plant, either intake necessitating considerable expenditure in piping, besides the construction of storage reservoirs. A separation of the surface water drainage and the sewerage systems is favoured in some quarters. The installation of a sewage farm with the necessary machinery and plant, with dust and sludge destructors, is also contemplated. Modifications are also likely to be introduced in connection with the present excellent potable water supply in the direction of the introduction of filtering beds, the water being at present unfiltered, and merely captured and stored in three reservoirs of a total capacity of 2,200,000 gallons.

Lighting.

THE Urban District Council of Whitchurch has decided to acquire the gasworks at a cost of £34,500.

THE Bradford Corporation has decided to advertise for a deputy manager for the gas works at a salary of £250 per annum.

THE plans of the new gasworks at Perth were finally passed at a special meeting of the Gas Commission held recently.

THE Eccles Town Council has decided to appoint Professor Dixon to test the gas supplied to the borough by the Salford Corporation.

THE Coventry Council has formally consented to the promotion of the Gas Bill, under which it is proposed to borrow £250,000.

THE Salford Borough Council has resolved to ask the Local Government Board to sanction the expenditure of a further sum of £50,000 on its electric light undertaking.

THE Morley Town Council has resolved to promote a Bill in next session of Parliament to obtain powers to purchase the local gas company's undertakings, and for other purposes.

THE Lighting Committee of the Brighton Town Council has appointed a Sub-Committee to consider and report upon the best means of lighting the public streets by electricity.

A LOCAL Government Board inquiry has been held at Wokingham into the subject matter of an application by the Corporation of the town for the sanction to borrow £1500 for the purpose of extending the local gasworks.

A PETITION to the Bedfordshire Corporation for the reduction of charges for electric current to 3d. per unit is being signed by consumers, who also consider that the rent charged for meters is 50 per cent. too high. The light has now been installed three years.

AT the monthly meeting of the Eccles Town Council, the proceedings of the Town Hall and Electric Lighting Committee included a recommendation that tenders be accepted to the amount of £9392 for the carrying out of works of electric lighting in the borough. The proceedings were confirmed.

AT the last monthly meeting of the Whickham Urban District Council the Committee appointed to inquire into the advisability of lighting the Marley Hill district with electricity recommended that lamps should be fixed as follows :—Marley Hill, 12 ; High Row, 6 ; School Houses, 2 ; Byer Moor, 8 ; and Marley Hill Hole, 4 ; making a total of 32 lamps. The price for the complete installation is specified to be £165 net, and a yearly charge of £55 4s.

A Local Government Board inquiry has been held at Southowram into the application of the District Council for sanction to borrow £2700 for street improvements, and £500 for public lighting purposes.

A Local Government Board inquiry was held at Croydon on Friday, the 7th inst., into the application of the Town Council to borrow several sums —amongst others £5000 for electric lighting purposes.

Consent has been given by the St. Faith's District Council to the scheme of the Norwich Electricity Company, who propose to apply for powers to extend their mains to Catton and Sprowston.

The Windsor Electrical Installation Company has just completed a contract for the supply of steam from the central lighting station to one of the Windsor hotels for laundry, heating, and cooking purposes.

The Mumbles (Glamorgan) Local Board has received an offer from Messrs. Weaver and Co., for the electric lighting of a large area of the district at a cost not to exceed the amount at present paid by the Council for gas.

The Dundee Town Council has decided to purchase a large piece of ground to the east of the present gasworks at a cost of £9000, exclusive of the annual feu duty, in order to carry out certain proposed extensions.

Owing to the omission to lay down in duplicate the plant supplying Maritzburg with electric light, that town's lighting arrangements have recently been in serious danger of breaking down. For some time the apparatus has been running under considerable difficulties, and the attempts of the engineers to obtain some fresh coils in Durban or in Johannesburg having failed, they have been forced to resort to makeshift constructions out of such materials as were locally available until the requisite coils arrive from England. Their present difficulties will doubtless enforce the necessity existing in all such cases of duplicate installations if intermission in the lighting services of towns is to be avoided.

Personal.

Mr. W. A. Peake has been appointed Inspector of Nuisances for the rural district of Gnosall.

Mr. T. G. Dickson has been appointed Medical Officer of Health for the urban district of Hay.

Mr. W. F. Ward has been appointed Medical Officer of Health of the Blyth district of Worksop.

Mr. J. R. M. Richmond has been appointed Medical Officer of Health for the rural district of Overton.

Mr. Walter Crowther has been reappointed Inspector of Nuisances and of Dairies and Cowsheds for the Urban District of Shelf, at a salary of £20 per annum.

Mr. R. Lord has been appointed Inspector of Nuisances for the borough of Loughborough.

Mr. E. T. Whitaker has been appointed Medical Officer of Health for the rural district of Blymhill.

Mr. H. N. Edwards has been appointed Medical Officer of the Flanstead district of Hemel Hempstead.

The salary of Mr. Hingley, Sanitary Inspector for Darlaston, has been increased from £80 to £95 per annum.

The Atcham Rural District Council has increased the salary of its Surveyor, Mr. John Morris, to £200 per annum.

Mr. C. F. Gettings, District Surveyor to the Norfolk County Council, has been appointed an Assistant Engineer on the Grand Junction Canal.

Mr. Roger K. Hamilton, of Hasland, has been appointed Medical Officer for the Hasland District of Chesterfield at a salary of £17 per annum.

The Local Government Board has sanctioned the reappointment of Dr. J. T. Haworth as Medical Officer for the Urban District of Filey, at a salary of £20 per annum.

Mr. Charles Wood has been promoted from the position of deputy-manager to that of Gas Engineer to the Bradford Corporation at a salary of £600 per annum.

Dr. Charles L. B. Stares has been appointed Assistant Medical Officer at the Infirmary under the Clapham and Wandsworth District Council at a salary of £120 per annum.

Mr. J. F. Stowe, C.E., has been appointed Engineer and Surveyor to the Urban District Council of Bridlington, in succession to Mr. R. R. Brown, who held the office for eight years.

Law Cases.

A DISPUTE ABOUT DRAINS.

Mr. Huxley, of Theydon-grove, Epping, Essex, was summoned at the instance of the Camberwell Vestry for having neglected to comply with a notice served upon him under the provisions of the Metropolis Local Management Acts requiring him to reconstruct the drain of some premises in Trafalgar-road, Camberwell.

Mr. G. W. Marsden, solicitor to the Vestry, appeared in support of the summons, and the defendant was represented by Mr. A. Lincoln Reed, instructed by Mr. H. I. Sydney.

It appeared from the evidence that in the early part of last year the defendant carried out some sanitary work at the premises in question—a public-house—at the instance of the Vestry. Ultimately the Sanitary Inspector required that the drainage of the premises should be reconstructed, a request which the defendant's surveyor considered ought not to have been made, he being of opinion that the drain was sound. The formal notice from the Vestry requiring the reconstruction of the drain was served on the 14th of June last. A few days before that date the defendant had entered into a contract for the sale of the premises, and in July the sale was completed.

At the close of a long hearing Mr. HOPKINS remarked that the action of the Vestry in proceeding against a person who was no longer the owner of the premises seemed to him to be trivial and unnecessary from every point of view. The Vestry seemed to have proceeded because there was a case on their books in which their notice had not been complied with, and without any regard whatever to the facts of the case. The proceedings seemed to be taken not for the purpose of getting the drain put into repair, but for the purpose of getting a penalty from a gentleman who was no longer the tenant of the premises, and who no longer had any power over the drain. If the Vestry said the drain was still defective, they could serve fresh notices upon the new occupier, but no amount of penalties and no amount of hammering at Mr. Huxley could have any effect upon the drain. The defendant would have to pay a penalty of 5s. and 2s. costs.

Notes and Queries.

[Subscribers have the privilege of obtaining advice in this column on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed to THE EDITOR, "Notes and Queries," THE SANITARY RECORD, 5, Fetter-lane, London, E.C.]

NOTE.—If an answer be required immediately, a stamped addressed envelope must be enclosed, when we will endeavour to furnish a copy of the answer by post, as owing to the large number of queries received we cannot guarantee the insertion of a reply in the succeeding issue.

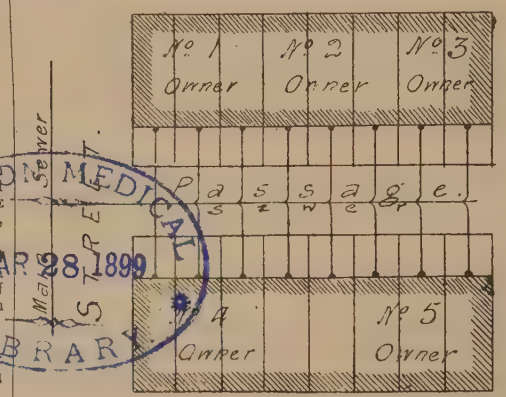
926.—SEWAGE FARMING: VENTILATORS ON SUBSOIL DRAINS.—"T. W. N." writes:—"Will you please inform me if it is necessary to bring up ventilators from subsoil drains in land laid out for sewage irrigation, as shown in sketch. In our sewage works, which for some years have been a source of trouble owing to the impurity of the effluent, these ventilators were fixed as shown. On my appointment a few months ago, I took out all the ventilators except those at the head of the drains, and the effluent showed considerable improvement. The Council, however, have now ordered the ventilators to be replaced. Is not the ventilator at the head of each drain sufficient?"

Answer.—It would have assisted us very materially in advising our correspondent if he had furnished us with a plan drawn to scale, as we are unable to ascertain whether the drains referred to are main subsoil drains or they are tributary subsoil drains; nor can we find from the rough sketch sent us (not reproduced) what was the distance apart at which the ventilators were constructed. On the general question, however, we are of opinion that the ventilators would be detrimental to the successful purification of the sewage, and that, as a matter of fact, the sewage would pass into the joints of the ventilating pipes without undergoing treatment. In stating this we, of course, assume that the pipes used were socketed sanitary pipes with open joints. Assuming, however, on the other hand, that the ventilators were properly constructed with water-tight joints, and placed, say, one chain apart, no advantage would be gained by their use. It is sometimes an advantage to provide a lamp-eye or shaft on the course of the drain, so as to be able to examine whether it continues to do its duty. Apart from this, it is not advisable to provide more than one ventilator, which may be at the head of the drain. Such ventilators are, however, rarely provided by sewerage engineers, as, besides being of doubtful utility, they interfere with the agricultural working of the ground.

927.—MUNICIPAL AND COUNTY ENGINEERS' ASSOCIATION: ADDRESS OF.—"E. A. S." writes:—"Will you please let me know the address of the Institute of Municipal and County Engineers? I am unable to find same in directory. Can you also tell me the charge for syllabus?"

Answer.—The offices of the Incorporated Association of Municipal and County Engineers are at 11, Victoria-street, Westminster, S.W., the secretary of the Association being Mr. Thomas Cole. A copy of the syllabus of examinations will be obtainable free, we believe, on enclosing stamps to defray postage.

928.—DRAIN OR SEWER: VESTING OF SAME.—"Stet" writes:—"I submit sketch showing a number of houses belonging to different owners, the drains of which houses are connected to a main drain laid along the passage or back street. In these circumstances, will the drain be repairable by the owners or by the Local Authority?"



MEDICAL LIBRARY MAR 28 1899

Answer.—The main drain laid along the passage or back street is a sewer vested in the Local Authority under Secs. 13, 15, and 19 of the Public Health Act, 1875, and it will be their duty to cleanse and keep the same in repair. The provisions of Sec. 19 of the Public Health Acts Amendment Act, 1890, do not apply in the case.

929.—MODEL BYE-LAWS AS TO OFFENSIVE TRADES: HOW OBTAINABLE.—"A. J. B." writes:—"Would you kindly inform me where I may obtain the Model Bye-laws referring to offensive trades and cleansing of footways?"

Answer.—The Model Bye-laws issued by the Local Government Board for the use of Sanitary Authorities, relating to Offensive trades, are published by Knight and Co., price 6d., and those relating to the Cleansing of footways are published also by Knight and Co., price 2d. Copies may be obtained from the Sanitary Publishing Company, postage 1½d. extra.

930.—NUISANCE FROM STANDPIPE: REMEDY.—"Anxious" writes:—"A complaint is received as to a nuisance caused by the water from a standpipe flowing over the ground and causing dampness in the foundations of a house adjoining. In winter the water frequently freezes on the surface of the road, and becomes dangerous to the public. The standpipe belongs to a waterworks company, and was put up with the consent of the adjoining owners. It is not out of repair, and the waste only occurs when pails are rinsed out, and the tap negligently left unstopped. The district is a rural one. (1) Has the Sanitary Authority any powers with respect to nuisances arising from frozen surfaces? (2) Can we compel the waterworks company to remove the standpipe, and fix it in a more suitable situation? (3) Or can we compel them to lay a drain to carry off the waste water?"

Answer.—(1) No; the Sanitary Authority have no

such powers. (2) The Sanitary Authority may suggest to the waterworks company the advisability of removing the standpipe to a more satisfactory situation, but will be unable to compel them to do so. The owner of the premises the foundations of which are injured may institute a claim for damages against the company. (3) If the standpipe is the property of the waterworks company, the Sanitary Authority may by notice require the company to abate the nuisance by providing a sufficient drain to take away the waste water.

---

931. — Sewers: Flooding: Compensation. — "D. T. G." writes:—"During recent heavy rains the sewers to which our drains are connected were so flooded as to cause their contents to be backed through our gullies, flooding the basements and cellars of a number of houses to a depth of from 4in. to 12in. Can we recover damages from the Urban District Council? If so, who should proceed, tenant or owner? If not, what steps can we take to prevent the nuisance recurring?"

Answer.—Unless it can be shown that the Urban District Council have been guilty of negligence in the maintenance of the sewer, a claim for damages caused by flooding owing to extraordinary storms could not be substantiated. The duty cast upon Local Authorities by statute as to the making and maintaining of sewers is not an absolute duty, but only a duty to use all reasonable care and diligence to keep the sewers in a proper condition. Assuming that the Local Authority in the case named have been guilty of negligence, a claim for damages may be made by the person who has suffered the damage, which may be either the tenant or the owner, or both. If the Authority are in default in not providing adequate or sufficient sewers, complaint may be made to the Local Government Board under Sec. 299 of the Public Health Act, 1875. It would be advisable, however, to first lay a complaint to the Urban Authority, and on their neglect appeal to the Local Government Board.

932.—Private Streets: Paving Expenses: Service of Notices.—"M. S." writes:—"Notices under Sec. 150 of the Public Health Act, 1875, were served on both the owner and occupier of certain premises abutting on a private street, and, not being complied with, the Council carried out the works. After the apportionment was made, it was found that the property in question had changed hands shortly before the commencement of the works, and that the occupier on whom the notice was served had left the premises at the same time. Do you consider that the service of the notice on the occupier would be sufficient to enable the Council to recover the apportionment from the present owner by taking summary proceedings, or should proceedings be taken to enforce the charge on the property?"

Answer.—Service of notice upon the occupier of the premises previous to the Authority executing the works is sufficient notice to comply with the provisions of Sec. 150 of the Public Health Act, 1875. The Local Authority have the option to serve either owner or occupier, and it is generally advisable to serve the notice upon both the occupier and the reputed owner. In this case notice has been properly served, and the expenses may be recovered summarily from the owner in default. It must be observed that unless notice has been given to the owner or occupier to do the work, the expenses cannot be recovered from the owner.

933.—Practical Sanitary Science Examinations: Syllabus and Books.—"E. H. G." writes:—"I should esteem it a favour if you would give me a synopsis of the subjects of the practical sanitary science examination of the Sanitary Institute, and a list of the books you recommend to be studied for the examination."

Answer.—A copy of the syllabus of subjects for the examination in practical sanitary science may be obtained free on application to the secretary of the Sanitary Institute (Mr. E. White Wallis), Margaret-street, London, W. We regret we are unable in the space at our disposal to publish it in this column. For a list of the books to be studied reference must be made to our answer to Query No. 781, in our issue of September 3rd, 1897.

934.—Destruction of Infected Bedding: Compensation.—"J. H. D." writes:—"We have been served with a magistrate's summons claiming compensation to the amount of 30s. for damages caused by destruction of infected bedding, which had been exposed to infection from a scarlet fever patient. We have not adopted the Infectious Disease (Prevention) Act, 1890. I have advised that, under Sec. 121 of the Public Health Act, 1875, we are not bound to give compensation. I believe the complainant relies on Sec. 308. (1) Has a court of summary jurisdiction power to hear such a claim in face of the option given in Sec. 121? (2) What is your interpretation of the words, 'he is not himself in default,' as in Sec. 308? (3) In case of appeal, will it not be to Quarter Sessions?"

Answer.—(1) Although Sec. 121 of the Public Health Act, 1875, appears to give permissive powers only to grant compensation, we are of opinion that, if a Local Authority, by virtue of its provisions, direct the destruction of any infected bedding or other articles, they are bound to compensate the owner of the articles destroyed. The owner

Agents Wanted where not already represented.

of the infected bedding will be able, we are of opinion, to substantiate a claim in respect of the articles destroyed, and the amount of compensation may be determined by justices under Sec. 181. (2) The words referred to apparently apply to cases where, owing to the default of the owner, the Sanitary Authority are compelled to interfere with his property. We do not think the words can be considered to apply in the present case. (3) Yes. See Sec. 269 of the Public Health Act, 1875, and the Summary Jurisdiction Act, 1879, which latter amends and in part repeals Sec. 269 of the Act of 1875.

935.—SEWERAGE OF HOUSES: MODE OF DEALING WITH OLD SEWER.—"J. F. M." writes:—"(1) I enclose sketch plan showing six pairs of semi-detached villas, the sewer to which is so defective as to require entirely relaying. In providing a new sewer, would you consider a sewer of 6in. diameter to be of sufficient capacity, or would you advise the provision of a 9in. sewer? The surface-water from roof, &c., is to be taken into the new sewer. (2) The defective sewer runs under coal-houses with cement floors and cemented yard surfaces, and is a 9in. pipe. How should it be dealt with? It would be very costly to take it up. (3) The disconnecting traps for drains are not in the right place, as a branch drain from a w.c. joins the main drain from each house at a point nearer the sewer than the trap. Can we legally compel the owners to continue their drains to the new sewer and put the disconnecting traps in the proper place, whether the drains are otherwise defective or not?"

Answer.—(1) We advise that a sewer of 9in. diameter be laid under the circumstances named. (2) The old sewer should be disinfected, flushed, and cleansed and blocked up at each end with cement concrete. As it will be broken into in different parts of its length, for the purpose of disconnecting the individual house drains, the openings thus made should be similarly plugged with cement concrete, so as to prevent as far as possible its becoming infested with vermin, such as rats, &c. The old sewer, if so treated, need not be taken up. (3) We should advise that the Authority require the owners, under Sec. 23 of the Public Health Act, 1875, to provide sufficient drains to each house, and for that purpose to take up and relay the disconnecting trap at a point below the lowest junction of each branch drain with the main drain.

TO OUR READERS.

The Editor solicits the co-operation of readers in making THE SANITARY RECORD *more attractiv by means of pen-and-ink sketches, photographs, and diagrams. There are many phases of sanitary work which lend themselves admirably to illustration. By this means not only individual articles, but the journal as a whole will be heightened.*

Contracts Open.

The dates given below are the latest up to which tenders can be received.

GLASGOW, January 17th. — Sewer. — The District Sanitary Office, 28, Cochrane-street, Glasgow.

MAIDENHEAD, January 17th.—Drainage.—Mr. Percy Johns, A.M.I.C.E., borough surveyor, Guildhall, Maidenhead.

BRIDGWATER, January 18th.—Sewer Work, &c.—Mr. Wm. Coles, Council's inspector, 2, Grosvenor-villa, Wembdon-road, Bridgwater.

LIMERICK, January 18th.—W.C.'s and Drains.—Mr. W. E. Corbett, C.E., M.R.I.A.I., city surveyor, 28, Glentworth-street, Limerick.

BIRKENHEAD, January 19th. — Sewer, &c. — Mr. Charles Brownridge, A.M.I.C.E., borough engineer and surveyor, Town Hall, Birkenhead.

HURST (LANCS.), January 20th.—Drainage Works.—Mr. Edward Garside, A.M.I.C.E., Town Hall-chambers, Ashton-under-Lyne.

LONDON, N.W., January 24th.—Works and Materials.—Mr. S. Slater, Public Offices, Hendon.

LONDON, N., January 25th.—Sewers.—Mr. P. E. Murphy, engineer to the Council, Coombes Croft House, 712, High-road, Tottenham.

LONDON, S.E., January 25th.—Sewer.—The Engineer's Department, County Hall, Spring-gardens, S.W.

MIDDLETON (LANCS.), January 26th. — Sewerage Works.—Mr. H. Leonard Hinnell, M.I.C.E. (Hinnell and Murphy, C.E.), 41, Corporation-street, Manchester.

KEIGHLEY, January 31st. — Sewers, &c. — Messrs. Barber, Hopkinson, and Co., civil engineers and surveyors, Craven Bank-chambers, Keighley.

Vacancies.

CLERK OF WORKS (SOUTHAMPTON, January 17th).—For the Harbour Board. Salary £2 2s. per week. Mr. A. H. Skelton, clerk, Harbour Board Offices, Town Quay, Southampton.

DRAUGHTSMAN (GOLD COAST, January 17th).—For Public Works Department, Gold Coast, West Coast of Africa. Salary £250 per annum for first eighteen months, £275 for the next eighteen months, £300 for any further period for which he may be engaged. Crown Agents for the Colonies, Downing-street, London, S.W.

DRAUGHTSMAN, &c. (HARTLEPOOL, January 20th).—Salary £2 2s. per week. Mr. H. C. Crummack, A.M.I.C.E., borough engineer, Town Hall, Hartlepool.

SCHERING'S NEW DIETETIC.

This is a new albumen preparation for domestic use. Its constituents, similar to milk, especially Human Milk, give it a peculiar value.

SANOSE

SANOSE is an odourless and tasteless white powder, forming an emulsion when stirred in water. THE MEDICAL PROFESSION strongly recommends it in cases of Anæmia, Dyspeptic troubles, Consumption, and in Cachectic Women.

For literature see "THE THERAPIST," November, 1897, and January, 1898.

Price 1s. per ounce; 3s. 6d. per 4 ounces.

Apply to all Chemists and Druggists, or to **A. & M. ZIMMERMANN, 9-10, St. Mary-at-Hill, London, E.C.**

ENGINEER (ST. ALBANS, January 17th).—For the Corporation. Salary 40s. per week, with house. Mr. A. H. Debenham, town clerk, St. Albans.

ENGINEERING ASSISTANT (BIRMINGHAM). — Salary £3 per week. Mr. John Price, city surveyor, The Council House, Birmingham.

ENGINEER'S ASSISTANT (SALFORD, January 20th).—Salary £120 per annum. Mr. Saml. Brown, town clerk, Town Hall, Salford.

RESIDENT ENGINEER (BEDWORTH, January 18th).—For the Foleshill Rural District Council. Mr. Alfred P. Oswin, clerk, Foleshill, near Coventry.

COMPETITIONS.

BELPER, May 1st.—Sewage Disposal.—The Belper Urban District Council offer first premium (£52 10s.) and second premium (£26 5s.) for the two best schemes for the disposal of the sewage of the district. Plans and report to be sent to Mr. Joseph Pym, clerk, Belper, carriage paid, by May 1st. Further particulars on application.

THE DRAINAGE OF VILLAGES.

BY

WILLIAM SPINKS, Assoc. M. Inst. C.E.,

Member of the Incorporated Association of Municipal and County Engineers; Member of Sanitary Institute Lecturer on Sanitary Engineering—Yorkshire College—Victoria University; President of Sanitary Engineering Section of the British Institute of Public Health, 1895.

SYNOPSIS OF CONTENTS.

PART I.—Statutory Powers—Pollution of Streams—In case of Failure to Provide Schemes—Existing Sewers—Present Means of Disposal—Composition of Sewage—Self-purifying Power of Rivers.

PART II.—Areas of District to be Sewered—Power to enter Private Lands—Works without District—Special Drainage Districts—Power to Agree with neighbouring Authority to take and deal with Sewage—Joint Sewerage Boards—Rainfall—The Geological Character of the District—Present and Prospective Number of Inhabitants—Supply of Water—Sanitary Appliances—Position of Outfall Works—Power to Purchase Lands—Borrowing Powers.

PART III.—Requirements of a Sewerage System—Depths—Gradients—Lines—Sewers and their Jointing—Manholes—Flushing—Ventilation.

PART IV.—Sewage Disposal—Purification through Land—Tanks—Sludge—Filtration.

The SANITARY PUBLISHING COMPANY, LTD., 5, Fetter Lane, LONDON, E.C.

Price 2s. 6d.; by Post, 2s. 9d.

A HEALTHY HOME.

By FRANCIS VACHER, F.R.C.S., M.R.C.P., M.O.H., Cheshire.

CONTENTS.

CHAPTER I.—**Introductory:**—Health of the Individual and Family—How shall they be Housed Wholesomely?

CHAPTER II.—**Site. Soil. Aspect:**—Desiderata as regards Site—Constituents of Soil—Ground Water—Rainfall—Diseases connected with Ground Water.

CHAPTER III.—**Building Materials.**

CHAPTER IV.—**Construction:**—Foundation—Walls—Damp Course—Damp-proof Coating—Thickness of Walls—Size of Floor Joists—Drain Pipes and Gutters—Height of Chimneys.

CHAPTER V.—**Design and General Arrangements.**

CHAPTER VI.—**Warming: Lighting and Ventilation.**

CHAPTER VII.—**Hot and Cold Water:**—Source of Supply—Pollution in Transit—Cisterns—Filtering—Service Pipes.

CHAPTER VIII.—**Sanitary Requisites:**—Drainage—House Drains—Drain Testing—Disconnecting from Sewers—Soil Pipe—Closets—Baths—Sinks—Grease and Gulley Traps.

CHAPTER IX.—**Decoration and Furniture.**

CHAPTER X.—**Stables, Cowsheds, &c.:**—Lighting and Ventilation—Drainage—Space required for each Cow.

CHAPTER XI.—**House Cleaning.**

CHAPTER XII.—**Obligations of Householder and Sanitary Authority:**—Right of Drainage into Public Sewers—Examination of Drains—Removal of Filth—Abatement of Nuisances.

THE WHOLE WELL ILLUSTRATED.

THE SANITARY PUBLISHING COMPANY, Limited, 5, Fetter Lane, London, E.C.

SITUATIONS.

VACANT.

☞ *Advertisements of Situations Vacant are inserted at the rate of Sixpence per line (prepaid), minimum three lines — eight words to line. Special rates for a series.*

WANTED.

THE SANITARY RECORD *will be found an excellent medium for those who are desirous of seeking Situations in the Offices of Surveyors, Sanitary Inspectors, Sanitary Engineers, Architects, &c. The charge for such advertisements (prepaid) is Sixpence per line. Minimum three lines—eight words to the line.*

WANTED, TWO FIRST-CLASS RESPECTABLE REGISTERED PLUMBERS. Constant employment to suitable men.—Name, salary, and particulars, to T. F. MACAULAY, 97, George-street, Limerick. English preferred.

SANITARY ASSOCIATION OF SCOTLAND.

EXAMINATIONS IN SANITARY SCIENCE.

Examinations for Certificates of Competency in Sanitary Science are held each year as follows, viz.:—In Glasgow in April, in Edinburgh in October, and at such other time and place as the Board of Examiners may determine.

Entrance Fee £2 2s.

For further particulars apply to

GEORGE MIDDLETON, M.A., LL.B.,
Writer, 92, Bath Street, Glasgow,
Secretary to the Board of Examiners.

A Stamped Addressed Envelope must accompany all letters requiring an answer.

SANITARY INSTITUTE EXAMINATIONS.

SPECIAL Corresponding Classes for the **Practical Sanitary Science,** and **Sanitary Inspectors' Examinations** of the **Sanitary Institute, 1897,** conducted by a gentleman holding appointments as Urban District Council Engineer and Sanitary Inspector, holder of three certificates from the Sanitary Institute, First-class Honour Medallist Hygiene, &c. Hundreds of successes.—For all particulars, testimonials, &c., apply Mem. San. Inst., Office of THE SANITARY RECORD, 5, Fetter-lane, London, E.C.

SANITARY INSTITUTE EXAMINATIONS.

TUITION BY CORRESPONDENCE.

An Engineer and Surveyor (Mem. San. Inst.), Certificated Surveyor and Inspector, prepares students for these Exams. by Correspondence through the post.

Fees strictly moderate. Cramming studiously avoided.

The course of tuition is arranged so as not only to qualify the student for passing the exams., but what is of equal importance, viz., that he may become a thoroughly efficient Inspector.

On successfully passing the exams., all possible assistance and advice is given to help forward intending candidates for public offices.

Many of my old pupils are now filling positions with salaries of over £120 a year.

For terms, &c., address "C. E.," care SANITARY RECORD, 5. Fetter-lane, London, E.C.

BOROUGH OF DENBIGH. — THE

Corporation of Denbigh require a Competent and Certificated Person as INSPECTOR of NUISANCES, &c., at a salary of £80 per annum.

The person appointed must devote his whole time to the duties of the office, particulars of which may be obtained on application to the Town Clerk.

Candidates to forward on or before the 17th day of January, 1898, sealed applications, endorsed "Inspector of Nuisances," enclosing copies of recent testimonials, and fully stating qualifications, &c., to the Town Clerk.

Canvassing members of the Council is a disqualification.

J. PARRY JONES,
Town Clerk.

Denbigh, 5th January, 1898.

SEWAGE CLARIFICATION

AND THE

Purification of Water for all kinds of Manufacturing Purposes.

The E. H. RIDDELL SYSTEM.

Owners and Patentees:

L. HUGH BRISTOWE & CO., Limited,

Albany Buildings, 47, Victoria St.,

Notes.

IT is a serious matter to consider that that grim scourge, tuberculosis, is practically a new disease among cattle, for it enforces attention to the fact that, despite the earnest efforts that are being made to eradicate it, the malady has assumed its present alarming proportions within a comparatively short space of time. The author of a pamphlet on "Bovine Tuberculosis," which has just been published, looking back thirty-five or forty years, states that tuberculosis was then an unknown disease. There were, no doubt, "piners" and "wasters" among cattle, but tuberculosis, as we know it now, at that time practically did not exist. We may well pause over these considerations, for they compel us to institute comparisons with the dimensions attained by the disease at the present day; and though accurate figures are not available, and the estimates of the number of cattle affected vary within the widest limits, even at the lowest computation, the numbers are such as to give cause for the gravest apprehension.

OF course, it is possible to exaggerate the danger. We are far from being threatened with national disaster, as is the case in South Africa with regard to the rinderpest, or the public would soon wake up. As a matter of fact, the public are singularly apathetic, because no amount of theorising or pointing out possible sources of danger will touch them until they see proofs of the evil actually in their midst. But if this same public were to lay to heart the facts and the figures which have been irrefutably established by "men who know," they would be provided with material for serious thought. Here is one fact for instance, which is emphasised by Mr. Warnock, the author of the pamphlet to which we have referred, and which may be taken by way of illustration of the conditions which favour the spread of the disease. In our larger towns, he points out, while much of our milk supply is drawn from the country, a very large proportion of it comes from exclusively city dairies, where the cows, though tended no doubt with care, must inevitably suffer from their confined existence. Deprived of the health-giving pastures which are their natural sphere, and of the fresh air and sunshine which are the only sure preventives of tuberculosis, such animals must deteriorate in the long run; and consequently it is small wonder that from 20 to 70 per cent., according to varying estimates, of the stall-fed cows in our towns are infected with tuberculosis.

A MORE serious charge, if true, is that the infected carcases are not infrequently disposed of in city markets, which are conducted under the very auspices of the Local Authorities, whose duty it is to supervise the supply of butchers' meat. We have no doubt that there must be a good deal more laxity of practice in this respect than is usually suspected, though to what extent it would be hard to say; but the very suspicion of such a thing should lead to increased vigilance on the part of all sanitary officials, whose part it is to check such looseness, when known to exist. Of course, that is a state of things that would be stopped at once, if detected, by a conscientious public servant; but the other evil, the system of deriving the milk supplies of a large city from stall-fed cows, is one that is open and recognised, and it is time that steps should be taken to have it also done away with. It is practically hopeless to expect immunity from infection from supplies drawn from such sources, and the question is too serious to be shirked.

THE water supply of Alloa is drawn from a dam, the proprietor's rights over which were acquired by

the town some time since for a considerable sum. The waterworks were also enlarged and improved at a cost of about £30,000. Notwithstanding this lavish expenditure, the water supply of the place has been seriously endangered by the opening of a coal pit in the vicinity, the sewage of which, after a process of nominal purification, has been allowed to pass into the dam. The Authorities recently obtained the report of an analyst, which showed that the samples submitted to him were quite unfit for domestic use, as they contained a large amount of suspended matter. Two alternative schemes have now been proposed to remedy the evil; either to provide an additional settling tank for the purification of the sewage from the pit, or to lay a pipe whereby the sewage might be diverted to a stream some two miles off, instead of being allowed to pass into the dam at all. To us it certainly seems extraordinary that the scourings of a coal pit should, under any circumstances whatever, be allowed to enter the reservoir from which the town's water is drawn, for even with the most carefully-devised settling tanks the purity of the water supply will always be liable to pollution from this cause. We presume that the colliery must possess rights in the dam which are indefeasible; otherwise it is hardly credible that their commercial interests should be suffered to jeopardise the health of the inhabitants.

While on the subject of water supply, we note with interest the report of an action at the instance of the Western District Committee of the County Council of Haddington against the proprietor of the village of East Saltoun, to compel him to provide an adequate vater supply for the villagers. It seems that there were two wells in the village, one of which was closed some time ago, as the water was found to be unfit for domestic use. The other well was still suitable, but was practically unavailable for many of the inhabitants on account of its distance from their houses. The proprietor, anxious to discharge his responsibilities, had borings taken, with a view to providing a permanent supply for these houses, but without success. He then made arrangements for a cart being taken daily, with a large barrel or puncheon, filled from the only available well, to a convenient spot where the houses to be supplied could satisfy their requirements, the barrel being refilled whenever emptied. Was this a sufficient provision in the eyes of the law?

The Court has decided that, while the Local Authority was quite entitled to call upon the proprietor to provide the inhabitants of his houses with a proper water supply, he had done all that could be required of him in the circumstances. The arrangements adopted by him were certainly rather primitive; but it was not disputed that the water provided in the puncheon was both wholesome and sufficient for the simple needs of the few villagers for whose benefit it was designed. The Public Health Act, under which the proceedings were taken, did not specify the mode of supply; it was enough to satisfy the provisions of the statute if a sufficient supply of good water was brought within convenient distance of the houses. Neither was it averred that the owner was likely to discontinue the supply; on the contrary, he appeared to be anxious to discharge his obligation, the nature of which had to be considered in the light of the circumstances of the place. So the puncheon will continue its daily peregrinations, till nature provides a more efficient substitute.

It seems a new idea to seek light for the cure of drunkenness from the ancient world. Apparently, however, even in this matter, we have lessons to learn from the long-forgotten past. A lecture was delivered the other evening by Dr. W. L. Brown before the Society for the Study of Inebriety, on "Inebriety and its Cures among the Ancients," in the course of which the lecturer reviewed the social customs of ancient Egypt, Assyria, Babylon, and the early Saxons, illustrated with diagrams, and discussed the remedies adopted by the physicians of those far-off times to prevent the evil effects of drink. The result of these researches was to show that the ancients were much more successful in their "cures" than we have been in ours, and the curious thing is that "total abstinence" formed no part of their system. Verily, we do not grow wiser with the centuries!

We have received from Mr. Callison, the Superintendent of the Cleansing Department of the City of Manchester, a very interesting report of the work done during the year 1896—7 by that department. As our readers are doubtless aware, refuse destructors are in use in that city; and in order to avoid the expense of carting away the clinkers they are ground, mixed with lime, and made into mortar, with the result that a profit was earned during the year under review of no less a sum than £1678 18s. 11d. This example might be followed in other towns, and is another proof of the repeated assertion that there is a use for everything, if only we find it.

It also appears that the department has been successful in another direction, viz., the farm; and we quote from the report the following paragraph, which is indeed, as the Committee say, "satisfactory:"—"With regard to the Carrington Farm account, the land farmed by your Committee consists of about 400 acres, and the amount charged to the farm for rent during the year was £933 1s.; all other expenses in connection with the farm at Carrington have been debited to the farm account, and credit has been given for all revenue derived purely from the farm. It is satisfactory to note that a profit has been made upon the farming operations."

On Sunday night there passed away one of the men of the century. To many the Right Hon. Charles Pelham Villiers was only known as the "Father of the House of Commons," but to those whose memory goes back half a century, he was a central figure in a small circle of earnest reformers. With his politics we have no concern, but it is interesting to note that he was the first President of the Poor Law Board in Lord Palmerston's administration, the post carrying with it a seat in the Cabinet. His strong personality found full scope for exercise in this important office, and his contemporaries tell us that when he vacated the post, he not only had left his mark on Poor Law legislation, but he had earned such praises from the poor that would have made his reputation even if

he had never been associated with any other reforms. For the great services of his early days Wolverhampton retained him as a member long after he desired to be released from the cares of parliamentary duties.

The plague still continues its dreadful ravages in India. The number of deaths reported at Bombay last week was 450. The total mortality of the city showed a death-rate of 81·18 per thousand. This week a statement has been issued by the Authorities at home, to which we gladly give circulation. It states that some months ago reinforcements of doctors and nurses were sent to India for temporary plague work. The Indian Government has now telegraphed to the Secretary of State for eight more doctors, two more lady doctors, and twenty-five more lady nurses. The Viceroy adds that, if the plague should extend, more men and women doctors and more nurses will be required. The India-office has already on its lists the names of a certain number of volunteers, all of whom are ready to start at two or three days' notice. We are asked to state that the India-office invite other volunteers to send in their names in case further help is wanted at short notice. None but candidates possessing full medical or nursing qualifications can be accepted, and no volunteers are sent to India until they are found by the Medical Board to be fit for tropical service. The terms of appointment and other information will be sent to any qualified person who may apply to the Revenue Secretary, India-office, Whitehall, S.W.

The reports of the Medical Officers of seaside towns are always interesting, and we are not surprised that general satisfaction has been caused by the presentation of an interim report from Dr. Newsholme, Medical Officer of Health for Brighton, announcing that the mortality returns for the past year have fallen to the lowest point ever reached in the borough. Dr. Newsholme, in a letter to the Sanitary Committee, writes that as it will be a considerable time before his Annual Report can be issued, he thinks it will be of interest to state that the death-rate of Brighton—the municipal borough—during the year 1897 was at the rate of 15·0 per 1000 inhabitants. The lowest rate previously reached was 16·1 in 1896 and 1889. He adds: "The favourable climatic conditions of 1897 have undoubtedly helped in producing the above favourable result; but, when due allowance is made for this, a death-rate of 15 per 1000 is extremely satisfactory, especially when it is remembered that the municipal borough of Brighton has not the usual complement of suburbs within its borders, which must always have a lower death-rate than the more central parts of the towns, and that in this respect Brighton is handicapped from a statistical standpoint in comparison with other great towns."

Some interesting figures were given by Sir Alexander Binnie, on Monday last, before the Royal Commission appointed to inquire into the supply of water to London. Sir Alexander said he had devoted many years to the question of London water supply, and to the various schemes which had been brought forward from time to time. There were eight water companies in London, and in 1896 another body was formed under the Staines Reservoirs Act. The area of the Administrative County of London was 121 square miles. The population in 1861 was 2,808,862; in 1871 it was 3,266,987; in 1881 the figures were 3,834,194; in 1891 the population was 4,232,118; and in 1896 it was 4,413,118. Taking the whole metropolitan police area, the population in 1861 was 3,222,720; in 1871, 3,885,641; in 1881, 4,766,661; and in 1891, 5,633,806. From these figures he found that the population of the outer ring, which between 1861 and 1871 increased 49·5 per cent., and between 1871 and 1881 at the rate of 50·7 per cent., and increased between 1881 and 1891 at the rate of only 50·3; so that the whole population within the outer ring was increasing at a decreasing ratio. Water London contained 620 square miles, of which 426 were within and 144 without the area of Greater London.

Another point brought out was the strength of the monopoly of the present companies, and the vastness of the area occupied. We were told that the Southwark and Vauxhall Company had a total parliamentary area of 50½ square miles, of which 39½ were within the County of London, and 11 square miles without, and it was overlapped by the parliamentary area of the West Middlesex Company 17½ miles, by the Lambeth 41 miles, the Kent Company 7½ miles, and the Richmond Corporation two square miles. Within the Southwark area Lambeth supplied 19 square miles, and within the Kent Company's area 3½ square miles. Witness gave similar details respecting each of the companies, explaining that overlapping did not mean competition. The Lambeth Company had 104 square miles, of which 42 were within and 62 without London County area; Kent Company, 212 square miles, of which 38 were within and 174 without the County of London; East London, 139 square miles, 21 within and 118 without, and partially overlapped by the South Essex Company; the New River Company, 107 square miles, 25 within and 82 without; West Middlesex, 85 miles, 34 within and 51 without; the Grand Junction, 52½ miles, of which 31½ were within and 39 without; and the Chelsea Company, with 20½ square miles entirely within the County of London. There was, witness explained, actual competition between the Grand Junction and the West Middlesex Companies. Taking the figures in the aggregate the united companies had power to supply 770½ square miles, or 150 square miles more than the total area. The competition was only on 2½ square miles out of 620. The total population was 5,606,920 persons, and the quantity supplied 197,988,052 gallons, of which 79¼ per cent. was supplied within the London County, and 20¾ per cent. outside.

TO OUR READERS.

The Editor solicits the co-operation of readers in making The Sanitary Record *more attractive by means of pen-and-ink sketches, photographs, and diagrams. There are many phases of sanitary work which lend themselves admirably to illustration. By this means not only individual articles, but the journal as a whole will be heightened.*

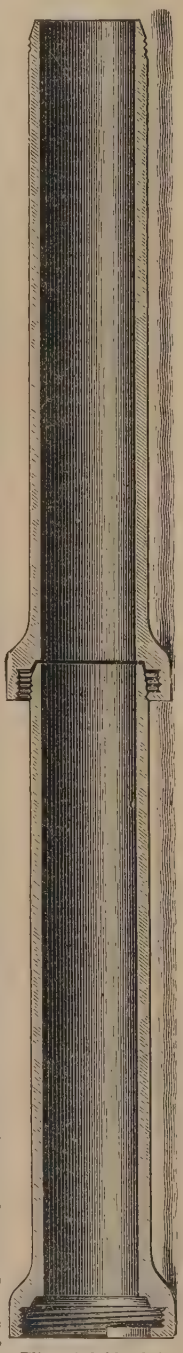
THE SANITATION OF DOMESTIC BUILDINGS.

By Frank Latham, C.E., M. San. Inst., &c., Assistant Surveyor, Borough of Margate.

CHAPTER II. (*continued*).

A variety of joints have been patented, and there is, as a rule, little or no fault to find with them, some of these recognised as successful being as follows:—

Fitzpatrick's patent joint is made as an improvement on the ordinary method of jointing pipes, and to dispense with the use of gasket, which in the usual joints is first placed between the spigot and socket, for the purpose of securing a uniform level in the pipes and preventing the cement entering and causing an obstruction. This joint is made by bevelling off the end of the spigot, a corresponding bevel and shoulder being formed at the back of the socket, giving a perfect continuity of bore, without the use of gasket. The joint is then finished in cement, and the liability of any of the material finding its way into the inside of the drain is reduced to a minimum. (Fig. A.)



Fitzpatrick's Joint

Hassall's "Double-lined" joint has a composite material cast on the spigot and socket; when the pipes are pushed together grout cement is run into an opening provided in the socket for that purpose. The grout cement then runs all round a groove left between spigot and socket, and makes a tight joint. (Fig. B.) Sykes' patent is a joint manufactured by the Albion Clay Company, Limited, and is on the principle of a screw which is cast on the spigot and in the socket in composite, and when well tightened together cement can be used in the space remaining to further secure the joint. (Fig. C.) Green's patent "Truinvert" pipe is a joint on the Hassall system, and when properly made affords an unusually safe and strong joint for house drainage purposes. It is formed, in the first place, by a lengthened double socket, one socket being deeper than the other, for the reception of the Hassall or composite joint, while the other forms a rest or seating for the end of the spigot. The pipes being thus placed together, a chamber is left between the composite and the end of the first socket for cement or other grout, which is admitted through two holes at the top of the sockets. (Fig. D.)

Self-adjusting joints, although not so extensively used for house drainage, are invaluable in some cases, and almost indispensable for laying drains in water-logged ground, as the work can be satisfactorily completed under water. The principal of these

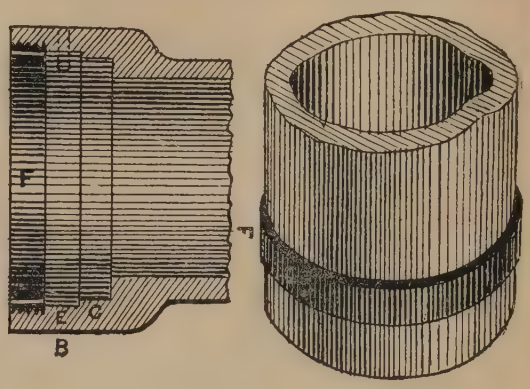


Fig. A

are Doulton's patent self-adjusting joint, which consists of a composite casting of spherical form on the spigot, and a lining of the same material in the socket, so that the spigot works in the socket on the ball-and-socket principle, and thus the joint is not injured by settlement of the ground. No cement is required.

The spigot and socket have only to be pushed tightly together and the joint is complete, consequently the pipes can be much more rapidly laid than in the case of hand-made joints. A little grease is sometimes used round the socket and spigot, in order that they may slip together easily. (Fig. E.) Messrs. Doulton have further improved this joint for house drains by their patent "composite" joint, which is laid and jointed in the same manner as their "adjusting" joint, but the sockets are of extra depth, leaving a space for the reception of an outer joint to be made in cement in precisely the same manner as an ordinary socketed joint, the composite taking the place of gasket. (Fig. F.) The material known as composite forming the principal feature of the Hassall and most patent joints, consists of sulphur, sand, and tar, in the proportions of 4, 2, and 1 respectively, which are mixed

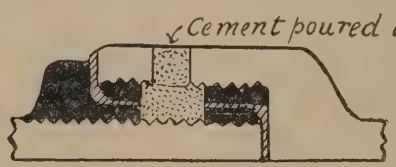

Fig. B

together while hot and moulded on to the spigots and sockets while the pipes stand in vertical position.

In iron pipes the joints should be made by first driving rings of twisted gasket or hemp into the sockets till they are half filled; cold rings of drawn lead is sometimes used in preference to gasket, but as hot lead is liable to melt these rings, the method is not to be recommended. Melted lead is then run in and the whole caulked up, and at the finish the joint should be full of lead. Great care should be taken that no lead gains access into the interior of

the pipes. The melted lead is run into the joints of small pipes by means of a fillet of clay being formed between the end of collar of the one pipe and the barrel of the other, leaving the cavity

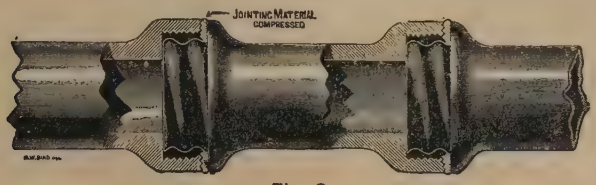

Fig. C

between the spigot and socket free for the lead to run round. For large pipes, in the place of the fillet of clay, which would not stand in making a large joint, gasket is twisted together, and after being dipped in puddled clay is fastened tightly round the pipe, and pushed against the collar to form a fillet, as in the former case.

The cement used for drainage works should be of the best Portland, finely ground, and weighing 112 lb. to the struck bushel, breaking with a weight of not less than 250 lb. per square inch after seven days' immersion in water. All cement for drain joints should be mixed up and allowed to stand awhile before use. If not so treated the cement is likely to blow. At the same time it should not be worked up a second time. In practice, it will be found that the addition of a small quantity of clean, sharp sand, used with discretion with the cement is beneficial, as the joints are not so likely to crack as when made with neat cement. The writer has had cases where, after drains have been satisfactorily laid, the joints on becoming set have blown and cracked owing to the heat of the cement, and thus rendering the drain defective.

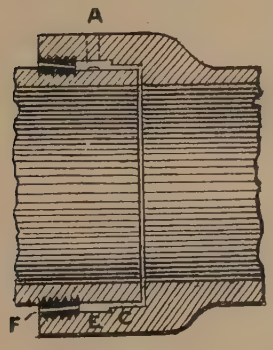

Fig. D

Concrete for drainage works should be composed of one part Portland cement well mixed while dry with six parts of good, sharp, clean gravel, or Thames ballast, the stones not to be larger any way than will pass through a 2in. ring, and to have a proportion of sand or fine gravel which will only just fill in the interstices of the large materials.

Often it is found necessary to carry a drain over an old filled-up cesspool of which the crown has been removed; unless proper precautions are taken, upon the ground subsiding the drain will be fractured. To prevent this it should be carried over the treacherous spot either by replacing the crown at the level required, or by bridging with a strong stone flag or iron girder with good bearings on each side. If possible, however, it is better to avoid such treacherous spots. The method of laying drains embedded with concrete is somewhat the same as already described. On the floor of the trench 6in. of good concrete should be laid, about 18in. in width. The pipes are then laid before the concrete becomes set, and the sockets sunk till the barrels rest firmly on the bed. The joints are then made in the same manner as before, and allowed to set, and, after testing any space between the pipes and concrete floor, which had been necessarily removed for jointing purposes, should be carefully filled in with concrete, which should then be brought round 6in. in thickness till the drain is perfectly surrounded. When this operation is completed it is advisable to again test the drain, in order to be assured that no fracture of either joints or pipes has taken place.

When the drain is more than 10ft. in the ground,

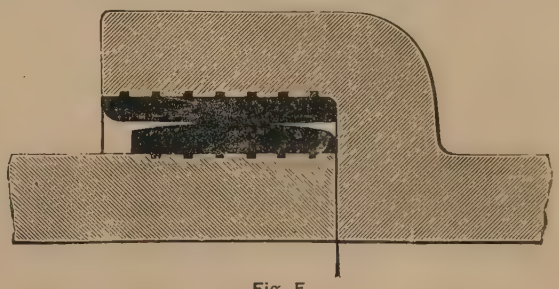

Fig. E

special provision should be made against the crushing of the stoneware pipes by compression from the superincumbent material. This can be done by using pipes made for the purpose, which are stronger than ordinary ones, being one-tenth the diameter in thickness. Should pipes of ordinary thickness be used they should have extra support by being laid in a bed of concrete brought half way up the sides, and in some cases surrounded with this material. It should be borne in mind that drains under houses should be laid in perfectly straight and direct lines, and with uniform falls from one end to the other. Thus assuming the pipes to be faultless and joints carefully made, the tube will be true and free from those defects which might tend to check the free flow of its contents, and thus safeguard against stoppages or fouling. As a matter of fact, all drains, including those outside of houses, should be laid in as straight and direct lines as practicable. With regard to the fall of house drains, it is advisable to have an inclination that will give a self-cleansing velocity to the sewage of 4ft. per second. A fall of 1 in 70 to a

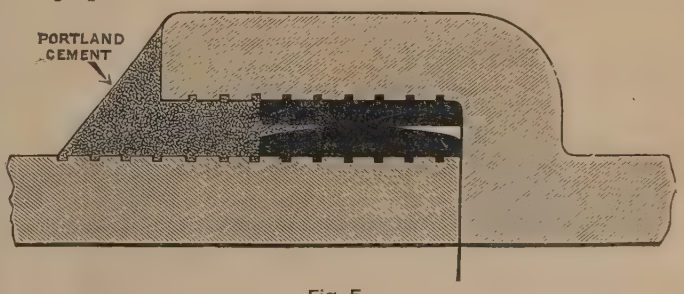

Fig. F

6in. drain, and of 1 in 50 to a 4in. drain, will effect this, when running full or half full. It is true that

a less fall is sometimes given, even up to 1 in 120 for 6in., and 1 in 80 for 4in. drains, giving a velocity of 3ft. per second, which by some authorities is considered sufficient, but the sharper fall is preferable, and lends itself better for ventilation purposes.

The determining the size of the pipe for house drains requires some consideration, there being as much hazard in making it too large as too small. Four-inch pipes should be the minimum size used, and it is quite sufficient to drain any fairly-sized house; they would scarcely ever run full, and are much more self-cleansing, and less likely to block than 6in. with the same quantity of sewage passing through. A drain running half-full bore is less likely to become blocked than one running less than half-full. This is owing to the fact that the deeper the water runs in a drain the quicker is its velocity, and quicker velocity means greater cleansing effect. The sectional area of a 4in. pipe is less than half that of a 6in., and therefore a 6in. drain would hold more than double that of a 4in. of the same length. A 6in. drain with a fall of 1 in 70 when running half full is capable of discharging 150 gallons of sewage in one minute, and with a fall of 1 in 120, 115 gallons. A 4in. drain with a fall of 1 in 50 will discharge 65 gallons per minute when running half full, and 50 gallons per minute with a fall of 1 in 80. When running full the discharge would be double. From the foregoing it will be seen that a 4in. pipe is more self-cleansing for ordinary houses than a 6in., besides not offering so much space for the collection of drain air or gas, nor surfaces for the deposit of filth to foul the drain. Drains 6in. in diameter should only be adopted under special circumstances for large establishments.

In order to set out the fall of a drain, the mason's spirit level and long straight edge are, as a rule, used. The spirit level should be placed on the straight edge, and this being laid on the top of the sockets of the pipes it should be raised at the lower end till horizontal. Then the measurement between the lower side of the straight edge and top of socket of pipe will represent the fall, and the length from the socket on which the other end of the rod rests to this point will represent the distance, and the one divided into the other will give the inclination. A convenient way is to fix a small cube of wood representing the fall required in a given length to the lower end of the straight edge. It is a mistake to merely lay the level on the barrel of the pipes, which is often done to obtain approximate falls without using a straight edge, as no uniformity of inclination can thereby be obtained.

A STRANGE ANOMALY.

Dr. T. Orme Dudfield, Medical Officer of Health, Kensington, in his annual summary, refers to a specially unhealthy area, known as Notting Dale, and emphasises the result of the strange anomaly which gives to the smallest of Local Urban Authorities powers denied to London Sanitary Authorities.

"The statistical information relating to the Notting Dale special area is summarised below, the relative figures for 1896 being also given by way of comparison. The population in 1896 was 3740; in 1897 it was ascertained to be 4000.

	1896	1897	
Births	142	... 130	
Birth-rate	38·0	... 32·5	per 1000 living.
Deaths	187	... 223	
Death-rate	50·0	... 55·7	per 1000 living.
Infantile death-rate ...	432	... 431	per 1000 births.
Zymotic death-rate ...	8·0	... 6·3*	per 1000 living.

"It has to be said, and it is said with regret, that no improvement in regard to the healthiness of the district, as judged by the death-rate, is as yet manifest, notwithstanding the efforts made in 1897 to improve the sanitary state of the houses and their surroundings. Nor is much change for the better, if any, to be expected until means shall have been devised to secure amelioration in the conditions of the home life of the people. It was hoped that this would have been brought about by the action of the County Council, to whom application was made by your Vestry that they should acquire the houses on the special area, under Part III. of the Housing of the Working Classes Act, 1890, and so be enabled to provide healthy homes for the inhabitants, whose tenancy could thus have been made subject to stringent regulations, as provided for in the Act. But this hope has been dissipated; the Council not having seen their way to undertake the beneficent task proposed to them. Your Vestry have, at present, no power to put this part of the Act into operation; it only remains, therefore, if anything is to be attempted, that steps should be taken to promote legislation to make the Sanitary Authority the Local Authority, sole or concurrent under Part III. It was a legislative mistake to endue the Council with exclusive power, and the sooner the mistake is rectified the better. It is a strange anomaly that the Sanitary Authorities of the metropolis should be denied powers enjoyed by the most insignificant Urban Sanitary Authority without London. Surely it cannot be supposed any Vestry or District Board would be unwilling to search out its dark places, and apply what appears to be the only remedy for such a state of things as exists in the special area, and probably in many another spot in this great city. It has been said more than once in these reports that the money cost of improved housing of the poor (if any) would be small in comparison with the good effected: such as has been effected—to cite but one, a notable instance—at Glasgow, where municipal lodging-houses for the dregs of the population, the outcasts of society, have been provided; the means of a comfortable, homely, and a social life, of a sort, being there secured to these poor creatures at a reasonable outlay for lodging and other accommodation, and this without entailing any burden upon the ratepayers."

We commend the above to the earnest consideration of all interested in the sanitary condition of the metropolis, and invite our readers to use our correspondence columns for the purpose of giving expression to their views.

East Grinstead.—The opening ceremony of the sanatorium took place on Thursday the 6th inst.

* The rate in 1896 was three times as great as that of the parish as a whole; the rate in 1897 was rather more than 3½ times as great.

NOTES ON
PRACTICAL SANITARY SCIENCE.

By WILLIAM H. MAXWELL.

Assistant Engineer and Surveyor, Leyton Urban District Council, Author of "Drainage Work and Sanitary Fittings," "Ventilation, Heating, and Lighting," &c., Certificates of the Association of Municipal and County Engineers, and Sanitary Institute.

No. 43.—REFUSE DESTRUCTORS.

(Continued from page 35.)

Whiley's Destructor.

This machine, shown in section in Fig. 7, is the patent[112] of Mr. Henry Whiley, the superintendent of the Scavenging Department of the Manchester Corporation, and is designed primarily with a view to labour saving. The arrangement differs from others in that there is no drying hearth, the refuse falling directly through hoppers to the furnace bars. A trough or hopper is provided at the back, into which the carts tip direct. A spout or tube is arranged, through which the refuse falls on to movable excentric grate bars, similar to Vicar's patent grate bars. These bars automatically traverse the refuse forward in the furnace, and finally push it against a flap door, which opens and allows it to fall out. The important difference between this furnace and others, therefore, is its automatic action, which aims at the reduction of manual labour to a minimum—the cells being fed, stoked, and clinkered automatically as above described.

A means of changing the speed of the bars from time to time is provided by friction gearing, in which the driven wheel running on the face of the driving disc, can be moved nearer to or further from the centre of the disc, which revolves at a constant speed. Some trouble has been experienced from the refuse sticking in the hopper, but no doubt that will be overcome. A more serious drawback to the system is that the grate bars have so much motion that they would let fine refuse drop through unburnt, and are therefore only suitable for places where, as at Manchester, they *screen* all the refuse, or at least select it. Exception may be taken to the mode of pushing out the clinker, as it causes the door to be continually flapping so that it fans cold air into the furnace. At the same time it is only fair to say that with screened Manchester refuse a very fair temperature, said to be about 1000 deg. Fah., is maintained, and the amount burnt is claimed to be ten tons per cell per day. Forced draught is employed by means of a Roots' blower.

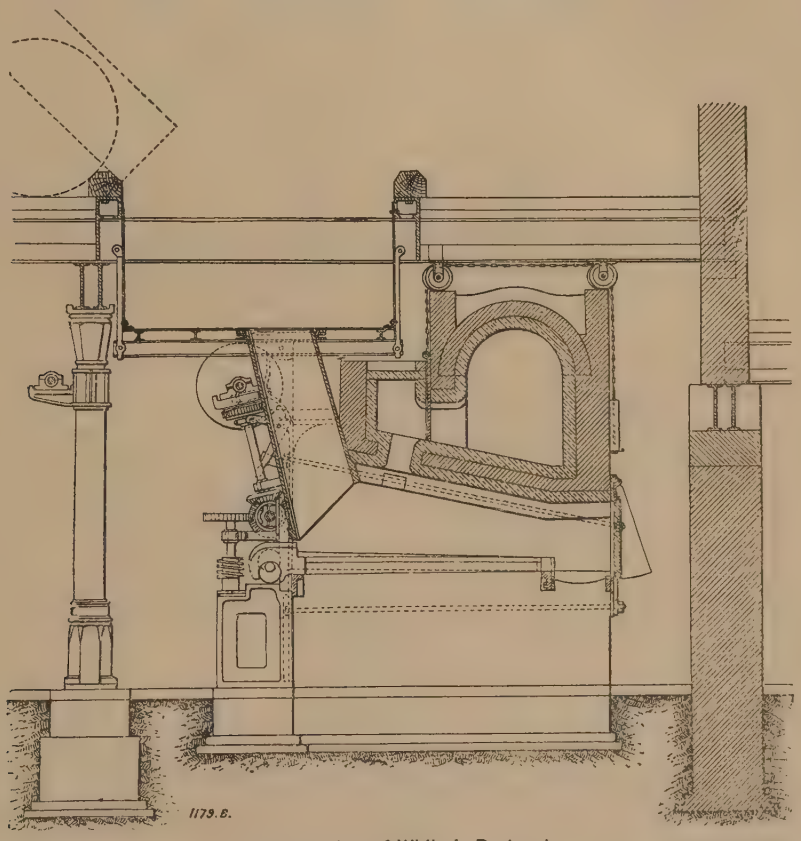

Fig. 7—Section of Whiley's Destructor

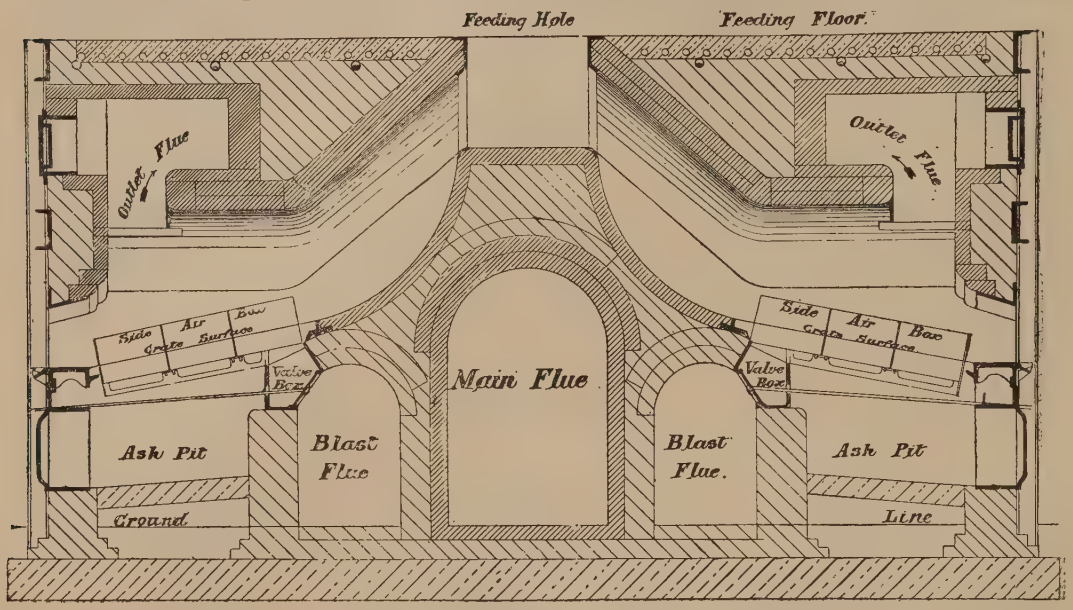
It will be noticed from the figure that the outlet into the main flue for the products of combustion is close to the shoot for the crude refuse — an arrangement which facilitates the escape of the objectionable empyreumatic[113] vapours unless the

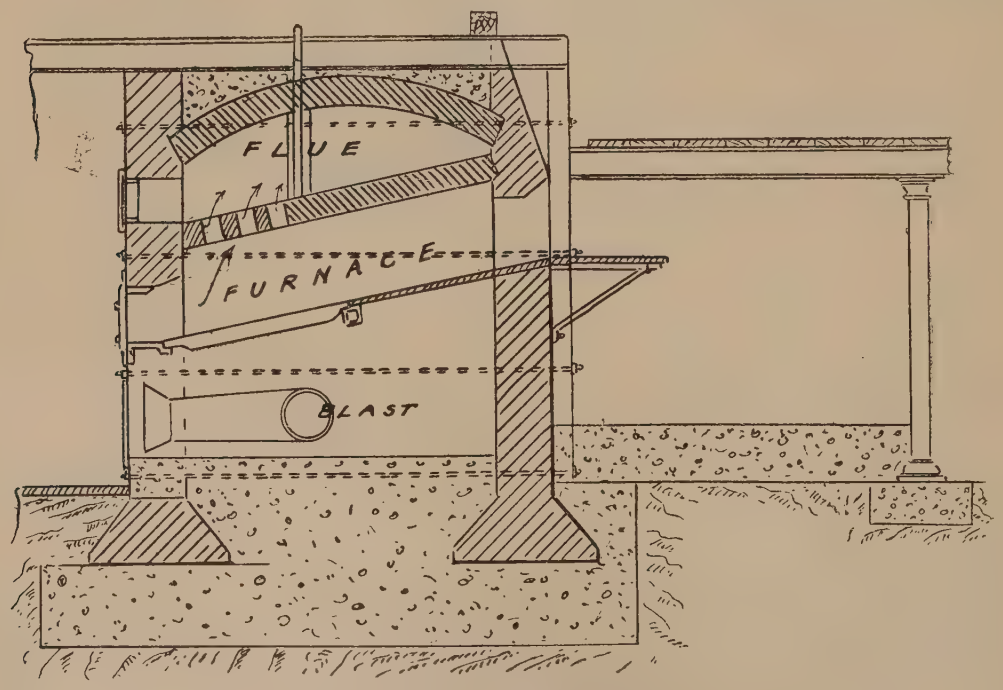
[112] Patent No. 8271, A.D. 1891.

[113] *Empyreumatic* = pertaining to the peculiar smell and taste arising from products of decomposition of animal or vegetable substances when burnt in close vessels.

heat of the flues can be maintained at a temperature sufficient to effect their decomposition and render them innocuous.[114]

The Manchester Corporation have laid down a perature" destructor adopted, either in whole or in part, at Oldham, Leeds, Bradford, Heckmondwike, Nottingham, Salford, Blackpool, Blaby, Calcutta, Berlin, Hamburg, and Edinburgh. It will be seen





Figs. 8 and 9—Horsfall's Destructor.

large installation of this form of furnace after having given it an extended trial.

Horsfall's Destructor.

The Horsfall refuse furnace[115] is a "high tem-

from the section (Fig. 8) given herewith that, although the general features of Fryer's destructor are retained, the details of the furnace differ from those previously described. This is particularly noticeable in regard to the arrangement and position of the outlets for the products of combustion, and in the introduction of a blast flue which forces air into a closed ashpit.

[114] It has been ascertained that a temperature of about 1250 deg. is required for this.

[115] Patent No. 8999 (1887); No. 14,709 (1888); and No. 22,731 (1891)

Speaking generally, the destructor consists of a furnace somewhat similar in dimensions and shape to Fryer's, with sloping drying floor and grates, bricked walls protected by cast iron side plates, perforated fire-brick arched roof, side flues, and an enclosed ashpit. The grate, which is composed of mechanical self-clinkering grate bars, is a little over 5ft. square, and at the back of this in the older forms is the drying floor of about 20 square feet in area, which in Horsfall's "improved design" is replaced by a "patent self-feeding apparatus"[116] worked by eccentric gear.

The accompanying diagram—Fig. 9—illustrates in section the destructor as originally designed by Mr. W. Horsfall, of Leeds, and a destructor of this description is in use at Oldham. The charging opening is situated in the back wall of the furnace, through which the refuse is thrown and distributed as required over the fire-grate and drying hearth.

PUBLIC HEALTH PROGRESS IN THE QUEEN'S REIGN (1837—1897).*

By T. RIDLEY BAILEY, M.D., of Bilston.

(*Continued from page* 40.)

TYPHUS FEVER.

Until the year 1869, typhus, typhoid, and simple continued fevers were included in the Registrar-General's returns under the one heading "Fever." Long before that time, however, it had been recognised that this term embraced different diseases which had been previously regarded as merely stages of the same affection.

In 1840 the late Dr. A. P. Stewart pointed out, in the *Edinburgh Medical and Surgical Journal*, the chief characteristics of typhus and typhoid fever, and showed that not only the symptoms but also the method of propagation, the class of persons mostly affected, the duration of the attack, and the mortality, were quite distinct.

These differences were not generally admitted till 1850, when Sir William Jenner, as a result of his inquiries, showed that the etiology of the one was not that of the other, that the two diseases only rarely prevailed together, and that the one did not communicate the other.

The importance of this discovery cannot be overestimated. It is most essential in preventive as in curative medicine that the correct diagnosis and the exact cause of every disease, but more particularly the contagia, should be definitely known in order that the proper steps may be taken to prevent their spread.

From 1870 the deaths from "Fever," therefore, have been classified under the headings, typhus, typhoid, and simple continued fever, but before that time no distinction is possible. Typhus fever or the old putrid, jail or hospital fever, is eminently infectious, and, as is now well known, is associated with overcrowding, dirt, want of light and air, and destitution.

In 1837, the disease prevailed in many parts of England, and in 1838 no less than 1271 per million of the population died of it. In the years 1846—48 a frightful epidemic occurred in Ireland on the failure of the potato crop. It spread to England, where, in 1848, 786 cases were admitted into the London Fever Hospital alone. In that hospital as many as 14,589 cases were treated during the period 1862—70. In Glasgow, too, the death-rate per million for the five years 1855—59 was 1265, and for the five years 1860—64, 1576.

These figures show the extremely fatal character of this most formidable disease. Since 1869, this fatality has markedly and continuously decreased, until now it has almost reached the vanishing point.

In that year the deaths in England and Wales were 4281, in 1885 they were only 318, and the mean rate for the quinquennium 1891—95 had actually been reduced to four per million of persons living. In Glasgow, too, to quote from "The Evolution of the Functions of Public Health Administration," by Dr. Russell, "we begin with 3607 deaths from typhus in five years (1865—69), of which 50 per cent. took place in hospital; we end with 70 in five years (1890—94), of which 94 per cent. took place in hospital. In other words, whereas in 1865 610 beds were kept full of typhus, and yet more than one-half of the total cases were allowed to run their pernicious course at home, for many years now two wards of fifteen beds each, or thirty beds in all, have sufficed to receive all the cases known to exist in Glasgow.

In fact, they are often empty for weeks, and they are never full. This is an example of the attainment of theoretical perfection in isolation—the largest proportion isolated of the smallest quantity of disease existing. This result is not wholly due to the persistent enforcement of isolation. Typhus is peculiar in that its infectivity may by change of environment be weakened almost to extinction. Cleanliness and fresh air make it comparatively harmless. The deadliest blow struck at typhus in Glasgow was the suppression of overcrowding.

Surely if sanitarians could lay claim to no other achievement, they would be entitled by this to an honourable place in the history of the Victorian era, for no one can fully estimate the saving to the community alone by such a record. The causes of typhus were the evil conditions in which the great mass of the people lived and were housed in the earlier part of the century—conditions that are not yet fully remedied in many of our large towns and manufacturing districts—crowded areas, narrow courts, close, stuffy houses, where light and air, wholesome water, through ventilation, and proper drainage were impossible. In such places it took up its abode as a permanent resident. The history of London and other large towns furnishes ghastly illustrations relieved by efforts after amelioration, as, *e.g.*, the formation of great open roads, cut right through, so that at least a current of fresh air and a fair amount of light might follow. Sir R. Thorne Thorne says, "that between 1856 and 1887 a sum of over fourteen million sterling has been devoted by the Metropolitan Board of Works to measures tending almost exclusively to the destruction of unwholesome property, and to the opening up of wide thoroughfares and breathing spaces in the crowded parts of the metropolis; and this sum does not include over two millions spent on the Thames Embankments; neither does it take any account of outlay in the erection of wholesome dwellings to replace un-

[116] Horsfall's Patent Self-feeding Apparatus (patent No. 20,207, 1892).

* Presidential address to the members of the Midland Branch of the Incorporated Society of Medical Officers of Health, October 7th, 1897.

wholesome ones—this latter work having been almost altogether undertaken by bodies and individuals having no access to the public purse. Thus, the company of which Sir Sydney Waterlow is chairman has, during the past twenty-five years, provided model dwellings for 25,000 persons ; some £440,000 has been spent within the City precincts in artisans' and labourers' dwellings, and such bodies as the Artizans' and Labourers' and General Dwellings Company and the Peabody Trustees have laboured in the same direction. Indeed, an intimate relation must be admitted to exist between these efforts and the disappearance of London typhus." Similar results, following upon similar actions, have been obtained in other places, such as Liverpool and Glasgow, where the expenditure of large sums of money in the removal of crowded, unhealthy areas has caused the dlsappearance of typhus, with incalculable benefit to the community in the prevention of unnecessary suffering and the saving of valuable lives.

Back-to-back houses, it must be admitted with regret, still exist. It is interesting to note that so long ago as 1849 Sir John (then Mr.) Simon, in connection with the disease under consideration, strongly condemned them. It would seem desirable that the adoption of the Model Bye-laws of the Local Government Board, by which it is provided that dwellings shall have a minimum space both front and back, should be compulsory throughout the country.

The experiences I have related not only justify but imperatively demand that Local Authorities should make any outlay that may be necessary for the abolition of crowded areas, and of those "Blind Houses" which violate the first principles of hygiene. In prosecuting such work as well as in the provision of free baths and wash-houses, and in the inculcation of more decent views of personal and domestic cleanliness, Sanitary Authorities would find ample scope for their energies. They will have their reward not only in adding to the sum of human happiness, but in the improved health and higher moral tone of the people. The words of Dr. Russell are very encouraging. "The practice of free washing of clothes wherever dirt is found in presence of any infectious disease and the steady enforcement of household cleanliness at all times, as well as the facilities afforded by an ample water supply and baths and wash-houses have raised the standard of domestic cleanliness in the poorer parts of Glasgow to an extent which only those who remember their former state can appreciate."

TYPHOID FEVER.

This gratifying record of the gradual disappearance of typhus fever—due partly to its differentiation from typhoid—is almost paralleled in the history of the latter disease. When once the fact was recognised that typhoid or enteric fever was essentially "the fever of fæcal decomposition," the way was open for its prevention by rendering it impossible that the poison from the excreta of a victim should reach others through either the water supply or milk or other food, or air.

In 1869, the first year in which, as already stated, the returns of the two diseases were separately recorded, 13,967 deaths in England and Wales were registered from enteric and simple continued fever, while in the quinquennium, 1876—80, the average yearly number was 8657, and the years 1881—5 only 6671. Or to give the result in another form; in 1869 the death-rate from enteric fever was 0·39 per 1000; in the decade 1871—80 the annual mortality was 0·32 per 1000 living at all ages; in 1888 it was 0·17, and in 1896 it was the same.

In 1866 was issued the famous report by the late Dr. Buchanan on the improvement to the public health of certain communities, following on a purer water supply, and a better system of sewerage, and the consequent abolition of cesspools.

Dr. Buchanan in the Ninth Report of the Medical Officer to the Privy Council, examined the death-rates from all causes, and particularly from certain diseases, in twenty-five towns, before and after the introduction of these sanitary measures. The result was an average reduction of 10·5 per cent. in the general death-rate in nineteen towns, but the decrease was specially marked in the mortality from enteric fever. In twenty-one towns there was an average decrease of 45 per cent. in the deaths from this disease.

For instance, the annual mortality from enteric fever for every 10,000 persons living, at Merthyr Tydfil, fell from 21 to less than 9 ; at Croydon from 15 to 5·5 ; and at Penrith from 10 to 4·5. This experience has been confirmed in some continental towns. In Hamburg, out of every thousand deaths, the rate for enteric fever has fallen from 48·5 to 10·5 ; in Dantzic from 26·6 to 2·3, while in Frankfort, the deaths from the same cause have fallen from 9 to 2 per 10,000 of the population.

Pettenkofer propounded the view that there was a distinct, if not causal, relationship between enteric fever mortality and the changes in the moisture of the soil from the rise and fall of the ground water. Buchanan, however, while admitting the possibility of an indirect connection, believed the true cause of the increase to be impurity of the drinking water ; and there is no doubt, as Baldwin Lathom has shown, that it is not the ground water itself that is the cause of the disease, but the impurities in the soil set in action by its varying level. During the last forty years various reports, with which you are all familiar, by Inspectors of the Local Government Board and others, have proved conclusively that epidemics of this disease have been due to a contaminated milk or water supply. Cream too, has been known to convey it, and even freezing does not destroy the bacillus, for ice and ice creams have also served as the media for infection.

It is also stated that typhoid can be transmitted to man by the milk of cows suffering from a corresponding disease ; and there can be no reasonable doubt that the virus may occasionally be conveyed through the air. Recent inquiries, too, have shown that oysters and other shell-fish may be impregnated with the poison and so become dangerous to man. An extremely interesting example of this came under my own notice some months ago, of which I gave an account in my last annual report, and which is quoted in this month's *Public Health*.

It is probable that, as in cholera, the specific poison of enteric fever has not its maximum virulence when first passed from the body, and it is astonishing how small a quantity is sufficient to produce an epidemic. Sir R. Thorne Thorne and Dr. Buchanan have shown that in the Caterham Valley outbreak from polluted water (in 1879) "an amount of specifically polluting matter, so infinitesimal in quantity as to be altogether beyond detection by chemical analysis, was fully potent for

mischief." It is well, however, for us and the public to remember the words of Dr. Russell in discussing so ably this question in relation to Glasgow :—"While we ascribe so large a share in the reduced fatality of enteric fever to the prevention of milk epidemics, these are, after all, what may be designated acute events arising from passing causes. The chronic causes of enteric fever, those which sustain it as an endemic, are the daily crop of nuisances essentially related to excrement removal which spring up within and about the house, which it is a great part of the business of the Nuisance Inspector to abolish from day to day ; and defects in the cleansing and scavenging of ashpits, courts, and closets, for which the Cleansing Department is responsible. The plodding work of the Sanitary Department and the intelligently developed system of cleansing, which has already been commended, therefore deserve their share in the allocation of merit." The figures given in support of this statement are most instructive : The death-rate per million from enteric fever was—for the 10 years 1865—74, 481·3; for the 10 years 1875—84, 417·4 ; for the 10 years 1885—94, 193·4 ; and in Dr. Russell's tables the following are the brief but most significant notes added : 1865, first Municipal Fever Hospital ; 1868, Cleansing Department organised ; 1870, Sanitary Department organised ; 1885, systematic drain testing and special summer cleansing begun ; 1889, privy system condemned ; 1890, Notification Act adopted.

Of simple continued fever it is only necessary to state that as a cause of death it exhibits a corresponding decrease. While in 1869 the rate was 0·24 per 1000, in 1888 it was 0·015. This is, no doubt, due largely to improved diagnosis, and I confess that—as a disease distinct from typhus, typhoid, or relapsing fever, I do not know what constitutes continued fever. In the New Nomenclature of the Royal College of Physicians (1896 edition), it is given simply as "Febricula," which surely is only a symptom, and I agree with Dr. Berry, of Wigan, that the name should be removed from the schedule of fevers under the Infectious Diseases Notification Act (1888).

(*To be continued.*)

Complaints have been rife this winter, from various quarters, of the way in which the streets have been cleaned—or, to speak more correctly, been left uncleaned. The winter has been mild and open, and there have been no difficulties to contend with in the way of snow or slush, and yet the accumulations of mud that have been allowed by the Authorities to defile the streets in places that we could name, have been a disgrace to municipal administration. And in this matter the Vestries of prosperous West End districts are not least to blame. It has been said that the great objection to washing the slime from the pavements is that the mud that is washed into the gutters will choke the drains. And therefore it is allowed to remain *in situ*! The apology is but a cloak for inertia. Dirt is never defensible, and its removal depends simply on the exercise of a little enterprise and a little contrivance. Why is it that in some places we never hear complaints, while others are notorious for their slackness ?

THE DISPOSAL OF ANIMAL REFUSE.

SOME PARTICULARS OF A GERMAN SYSTEM WHICH IS ABOUT TO BE ADOPTED IN NOTTINGHAM.

By Dr. Philip Boobbyer, M.O.H., Nottingham.

The Health Committee of the Nottingham Corporation have long felt the necessity of providing some more cleanly, economical, and generally efficient means of dealing with the carcases of horses, with condemned (unwholesome) meat of various kinds, and other refuse animal matter, than has hitherto been afforded.

In the early part of 1897 I reported to the Committee that a patented German invention was on the market, though not yet sold in this country, for reducing horse and other refuse flesh and organic material, by the aid of superheated steam. I was thereupon instructed to obtain what particulars I could, respecting the cost and working of the apparatus, for the information of the Committee.

With the aid of the local agent of the German patentees, Mr. Richard Simon, of Zulla-road, Nottingham, I found that, although there was one installation of the apparatus about to be established at Bristol, there was none in actual work in the United Kingdom. There was, however, a considerable amount of reliable information to be obtained, both at home and abroad, from persons who had seen the apparatus at work, and, this having been laid before the Committee, they finally decided on October 29th, 1897, to send a deputation, from their own body, to Germany, to inspect the plant in operation.

The deputation consisted of the Chairman, Vice-Chairman, Mr. Alderman Jelley, Mr. Councillor Hunter, and the writer. It was decided that the deputation should proceed to the town of Essen, on the borders of Westphalia and the Rhine Province, where three of the apparatus were stated to be in full work, in the public abattoirs of that town. They accordingly started on Tuesday, November 9th, and travelling *viâ* Calais and Brussels, reached Essen on Thursday evening, November 11th.

The town of Essen contained, at the census of December, 1890, a population of 78,723, which is now estimated to have increased to close upon 100,000 persons. It is well known as the headquarters of the celebrated Alfred Krupp, in whose works nearly 50,000 of the inhabitants of the town are said to be employed.

Early on the morning after their arrival, accompanied by the Nottingham agent and two chief officials of the firm who make the apparatus, the deputation proceeded to the abattoirs on the outskirts of Essen, and found there, as stated, three of the apparatus in full work.

Each apparatus consists, essentially, of a jacketed cylinder 10ft. long by 4ft. 6in. diameter, known as the steriliser or disinfector, within which is a freely revolving perforated drum, furnished at its lower part with a heavy iron roller for grinding and expressing, and across its cavity with projections for stirring the contents. The cylinder is horizontally suspended on short steel shafts or trunnions, and is either oscillated or turned (as the nature of the work to be done may require) by means of reversing or continuous cogs and an archimedean worm.

Connected with this essential part of the

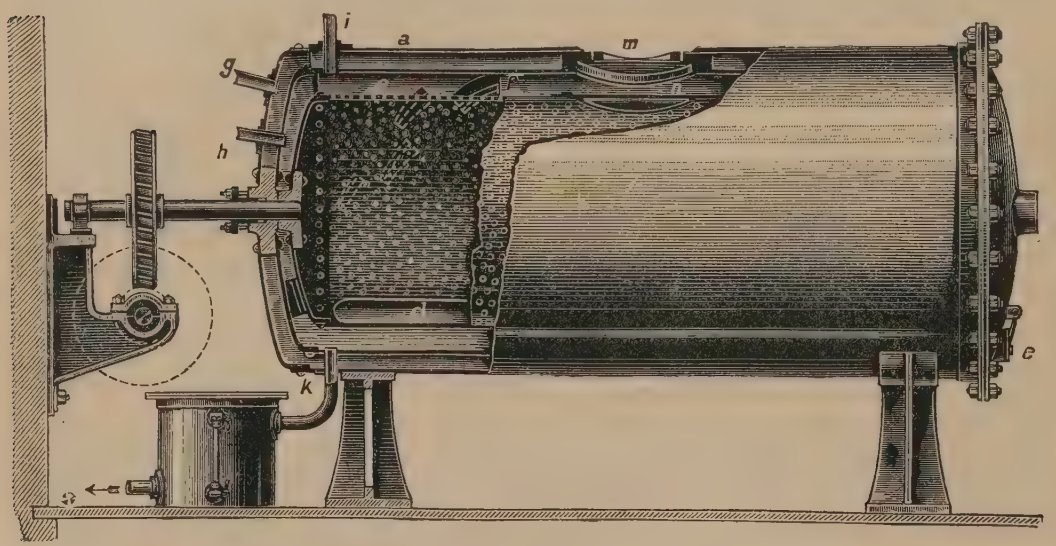
mechanism are closed iron vessels, known as "recipients," and "separators," for receiving and separating the fat and gelatin produced, which is forced into them by steam pressure, also a Lancashire boiler, and a small horizontal engine, with the necessary steam piping, shafting, ejectors or suction and pressure pumps (for fumes), condensers, &c. Each apparatus requires about a 2-horse power to actuate it.

The apparatus is now made only in two sizes (instead of three, as stated in the original prospectus). The price of each apparatus, less boiler, engine, and other accessories mentioned above, but, otherwise complete, fitted up in working order in this country, is :—No. 1 size, with capacity for two tons of raw material, £1084. No. 2 size, with capacity for one ton of raw material, £882. Two apparatus of No. 1 size, when sold together, are quoted at £1295 the pair.

The practical operation of the mechanism is conducted in the following manner :—

A load of flesh, fat, bones, &c., amounting to some 30 cwt. or 40 cwt., *i.e.*, a mass corresponding to the bulk of from three to four horses, or any lesser quantity that may have to be dealt with, is introduced, either through the manhole on the upper surface of the cylinder, or, when it is necessary to introduce an entire carcase, as in dealing with infected animals, by opening the whole end cover of the cylinder and allowing the carcase to slide down a shoot into its cavity. The inner space is now closed by a slide, and the whole cylinder by means of a clamped and steam-tight cover. Before describing the admission of steam to the jacket and drum, it may be as well to mention that from 45 lb. to 52 lb. steam (3 to 3½ atmospheres) is commonly used, but that 75 lb. steam (five atmospheres) is sometimes applied—the former when time is no object, the latter when it is. Steam, then, of from 45 lb. to 75 lb. is first admitted into the outer jacket, to warm the cylinder and its contents, the fume ejector (carrying offensive gases and vapour through a washer to the furnace) is opened, and the cylinder is caused to revolve or oscillate slowly

In the more recently constructed apparatus suction and pressure pumps are used for conveying the fumes to the boiler fire. After the temperature of the interior has been raised to about boiling point —212 deg.—the ejector is shut off, steam is introduced into the cavity of the cylinder, and the process of steam digestion commenced. After the latter has been continued for some three or four hours the fat and gelatin, which are now completely separated, are forced out into their above-mentioned receptacles (recipient and separator) by steam pressure. The steam is then shut off from the interior and supplied only to the jacket in order to dry the residual "manure" remaining in the interior, and the fume ejector is opened. After the lapse of from two to five further hours—the length of this period varying with the temperature of the steam, and the mass of material to be dried —the whole of the residuum will have been completely desiccated, and forced by the roller through the perforations in the drum. This stage of the process being satisfactorily completed, the door at the end of the cylinder is opened, and the contents automatically discharged or removed by manual labour.



Apparatus for Disposal of Animal Refuse

The fat extracted from the carcases of the horses, and other animals commonly available, is of excellent quality, and fetches from 12s. to 14s. per cwt. The gelatin, chondrin, &c., cannot be used for glue-making, on account of the high temperature to which they have been exposed. They can be used only for the making of size. The dry residuum has been spoken of above as manure, but it is stated also to be an excellent, though somewhat rich food for pigs, fowls, and other creatures. It is sold at from 3s. to 4s. per cwt. (sacks included), in sacks measuring, when full, 2ft. 6in. by 1ft. The material scales almost uniformly 110 lb. to the bushel measure.

In addition to the process here described there is one by which the offals, abattoir manure and sweepings, blood and other organic detritus of the shambles, are reduced to odourless manure in similar cylinders and by similar methods to those

already detailed, except that no "recipients" or "separators" are called into use, there being no fat or gelatin worth mentioning to be obtained from the raw material to be dealt with. The product of this last process is said to be saleable at from 1s. to 2s. per cwt.

The fat produced by the first process is said to contain only about 1½ per cent. of water. The residual manure from the first process is reputed to contain: water, 6·2 per cent.; nitrogen, 6·47 per cent.; phosphoric acid, 13 per cent.

The manure from the second process seldom contains, it is said, more than 2 per cent. of nitrogen, and cannot therefore be of any great value, except perhaps for lightening heavy soils.

To give some idea of the business value of the first process, the following analysis of its actual test operation in a single apparatus of No. 1 size, and the result thereof, during a period of ten days (comprising 95½ working hours), has been worked out by Dr. Pöbel, of Cassel:—

Weight of flesh, &c., digested.	Description of animal yielding material.
23,430 lb.	Horses.
4,510 lb.	Horned cattle.
2,145 lb.	Swine.
165 lb.	Deer.
30,250 lb. (= 13 tons 10 cwt.)	

The digestion of this total yielded—

3,739 lb. fat = 33·4 cwt. (= 1 ton 13 cwt.)
5,896 lb. guano = 52·6 cwt. (= 2 ton 12 cwt)
? size.

33 cwt. fat at 12s. =	£19	16	0
52 cwt. guano at 3s. 6d. =	9	2	0
	28	18	0
58½ cwt. coal used at 6d. =	1	9	3
Gross	£27	8	9

Disinfection is so completely effected by the process of steam digestion, that, in Germany, the carcases of animals that have suffered from any of the infectious diseases, including glanders, are allowed to be disposed of in this manner.

To show, however, that the practice does not arise from a careless disregard of the dangers of infection, it may be mentioned that it is customary in many parts of Germany to raze to the ground all buildings in which glandered animals have been housed.

The Otte plants at Essen are attached to the public abattoirs of that town, and, with the latter, are owned by the municipality.

Although a large quantity of flesh and other material was in process of digestion in all the apparatus at the time of the deputation's visit, no offensive smell was perceptible at any part of the premises.

DIARRHŒA.*

By Alfred Hill, M.D., F.R.S.E., F.I.C., M.O.H., Birmingham.

I have frequently shown, in previous reports, that outbreaks of Summer Diarrhœa do not occur until the temperature of the ground has reached a certain point, and that they are closely associated with the careless feeding of infants. But the fact has been established that these two influences will not operate in a marked degree, unless insanitary conditions are also present. The most probable theory regarding the disease is that it is dependent on some micro-organism which resides in or near the surface of the earth, and which can only become active where there is dead organic matter present and after the temperature has become sufficiently high. Given these two conditions, it appears that the organism can become air-borne, and may be taken into the body with the food and drink, with the result that diarrhœa is set up. If, therefore, diarrhœal outbreaks are due to an organism that depends for its existence on dead organic matter, or in other words, on animal and vegetable refuse, it is obvious that to prevent visitations of diarrhœa, we must remove all those conditions which promote the retention of such refuse instead of its speedy removal. The most important of these conditions, as found in towns, are (1) unpaved and filth-sodden ground in proximity to houses; (2) accumulations of excreta in unsuitable positions; (3) stagnation of air both inside and around dwellings, by which organic impurities are able to accumulate in the air instead of becoming diffused.

On many previous occasions I have called attention to the occurrence of summer diarrhœa, especially in relation to the above points. Immediately after the recent outbreak of diarrhœa, I tabulated the results of 500 inspections of houses in which deaths from diarrhœa occurred during August. I found that in 158 instances there was a part of the yard or court which was neither paved nor cultivated. In most cases such ground is uneven, and allows rain water to lodge on it. Moreover, as a rule, it is not kept clean, house refuse, such as bedroom slops, bread, fish heads, tea leaves, and other vegetable refuse, and even excreta, being noticeable in some instances. The evil is also aggravated in a great many cases by the keeping of fowls, ducks, or pigeons close to the houses, and in confined situations. Now it appears to me that such unpaved and filth-sodden yards must be most suitable places for the development of an organism that requires organic refuse for its subsistence, and must therefore be an important factor in the production of diarrhœa. I therefore recommend, as I have done on previous occasions, that all yard surfaces be paved with some impervious material, such as blue bricks in cement, and that the keeping of fowls, ducks, or pigeons, near to houses, be not allowed.

I further found that out of the 500 houses examined 300 had pan privies, and 38 had ashpit privies. Now, in a pan or ashpit privy, even if it is well placed and well looked after, there must naturally be retention of fæcal matter for a considerable time, instead of immediate removal as in the case of a water-closet. Unfortunately, in most instances, these pan and ashpit privies are in very bad situations, being close to houses, and in confined, ill-ventilated positions. Moreover, they are often only imperfectly scavenged, refuse being noticeable around the pan in the space under the privy seat, as well as in the ash place, even after the excreta and house refuse have been collected. In many cases urine escapes on to the floor around the pan. Here, again, we have some of the most essential conditions for favouring diarrhœal mortality. The only satisfactory method of dealing with both pan and ashpit privies is

*Abstracted from the Report of the Health of the City of Birmingham for the third quarter of the year 1897.

to abolish them entirely, and to substitute some form of water-closet, and I recommend that such steps be taken as will cause this improvement to be rapidly carried out. But in the meantime I consider it imperative that the privies should be kept in better order, and for this purpose I recommend that the ashes from houses having pan privies be fetched away in the day time, and that the men who fetch them be made responsible for sweeping and swilling the privy, both in front of and under the seat, as well as for properly cleansing the ash-place, and for removing all refuse except such as is produced in the course of some trade process.

My inquiry showed that out of the 500 houses examined 301 consisted of three rooms or less, while only 23 had more than six rooms. Moreover, 290 out of the 500 had no through ventilation, and 281 opened into courts or terraces, and not into the street. Most of the houses in which diarrhœa occurred were, therfore, very small houses, with imperfect ventilation both within and around them. In and near such houses organic impurities from many sources are certain to accumulate, instead of being dispersed, as they would be in better houses where there is more air space and freer ventilation; and as diarrhœa is so closely associated with organic impurities it is but natural that such houses should suffer heavily from the disease. In seeking to improve the condition of things in these small houses two main points have to be borne in mind. Firstly, there must be sufficient air around the outside of the house, and facility must be given to this air to move freely, so that there may be no stagnation. Secondly, adequate provision must be made for the passage of a current of air through the various rooms of the house. In many of the older courts in the city the amount of space in front of the houses is miserably inadequate, in some cases less than 10ft. across measuring from the front of the house, while the means of ventilating the rooms are not effective, inasmuch as there are no back doors or windows. The only satisfactory plan of dealing with these houses is by demolishing a certain number in every overcrowded court, so as to increase the amount of open space and afford facilities for better ventilation by means of additional windows in the houses that remain. I therefore recommend that wherever houses in crowded courts are closed as unfit for habitation, efforts should be made to get them demolished rather than repaired; and that where the houses in a court are closely crowded together, but not in themselves unhealthy, they should be removed in accordance with the powers given with regard to obstructive buildings by the Housing of the Working Classes Act.

I am convinced that it is only by such means as I have just suggested that the diarrhœal mortality, and with it the general mortality, can be substantially lessened. I most earnestly hope and trust that the measures I have suggested will be carried out, and they will produce as I have no doubt they will, a real improvement in the health of all who live in the less favoured parts of our city.

Meteorology and Mortality.

The chief interest in the meteorology of the quarter lies in the intimate connection which is known to exist between climatic conditions and diarrhœal mortality. I have already alluded to the theory that the essential cause of diarrhœa is a micro-organism which has its home in the earth's superficial layer, but which remains inactive until the temperature of the ground, not of the air, has become high enough to favour its development. This view is certainly confirmed by the figures for the past quarter, which are as follows :—

Weeks ending.	Highest temperature of the air.	Highest temperature 4ft. below the surface of the ground.	Deaths from diarrhœa and enteritis.
June 5	70·0	48·5	14
,, 12	79·1	49·3	14
,, 19	81·0	50·2	4
,, 26	80·2	50·7	8
July 3	73·7	51·9	8
,, 10	68·0	52·2	6
,, 17	78·3	52·8	16
,, 24	76·6	53·2	42
,, 31	75·2	53·6	81
Aug. 7	84·4	54·5	160
,, 14	72·1	55·0	228
,, 21	68·8	54·9	224
,, 28	66·0	54·6	157
Sept. 4	65·2	54·4	89
,, 11	62·5	54·0	44
,, 18	63·8	53·3	44
,, 25	61·7	53·1	33
Oct. 2	65·8	52·9	26

A study of these figures will show that the relation between the air temperature and the mortality from diarrhœa is by no means constant, that is to say, that the deaths from diarrhœa do not rise and fall with the fluctuations in the temperature of the air. For instance, the air temperature in June was much higher than in July, yet the diarrhœal mortality was much lower. Even in August, also, the air temperature was but little higher at any one period than in June, while on the whole it was lower; yet in August the deaths from diarrhœa were something like twenty times as numerous as in June. On the other hand, it will be noticed that the ground temperature was rising steadily during June and July, that it reached its maximum in the week of greatest diarrhœal mortality, and that as soon as the ground temperature began to fall the diarrhœal mortality began to decrease also. The experience of the past quarter entirely strengthens the view that it is the temperature of the earth, not of the air, that determines the prevalence of diarrhœa, and, therefore, that the germ of the disease must reside in the earth's crust.

The mean temperature and the rainfall for each of the past three months are shown below :—

Temperature.

1897. Month.	Mean temperature for month.	Average for ten years, 1887-1896, inclusive.	Above or below the average.
	deg.	deg.	deg.
July	61·0	59·2	+ 1·8
August ...	60·1	58·5	+ 1·6
September ...	52·9	55·2	− 2·3

Rainfall.

1887. Month.	Rainfall for month.	Average for ten years, 1887-1896, inclusive.	Above or below the average.
	in.	in.	in.
July	0·95	2·51	− 1·56
August ...	3·81	2·85	+ 0·96
September	2.48	1·98	+ 0·50

A NEW DIETETIC.

In a recent issue of the *Deutsch Med. Wochenschrift*, Drs. Schrieber and Waldvogel dilate upon a new albumen preparation called "Sanose," the most recent addition to the many valuable therapeutic agents for which the eminent German *savant*, Schering, is responsible, and which Messrs. A. and M. Zimmerman, of 9-10, St. Mary-at-Hill, London, E.C., are with characteristic enterprise introducing to the medical profession of this country.

Sanose, it appears, is a combination of 80 per cent. casein with 20 per cent. albumose, and a combination of these two classes of substances—digested albumen (albumose) and casein—appears especially advantageous, because pure albumose, as well as Liebig's meat peptone, forms a peculiar combination with casein. Whilst pure casein on boiling with water gives a sticky caoutchouc-like mass, if well triturated with a fifth of its weight of albumose it loses this characteristic, and a completely suspended milk emulsion is obtained.

The peculiar behaviour of milk may possibly be thus explained. If milk is repeatedly shaken with ether, the fat may be gradually extracted without the milk losing its milky appearance. Consequently the milky appearance is not solely due to the suspended globules of fat. Moreover, the casein of milk is not separated by boiling the latter, which has been attributed to the combination of casein with calcium or phosphate of sodium. For some time, however, it has been known that milk exhibits exactly the same behaviour when completely freed from salts by dialysis. In milk, there is, however, besides casein, a comparatively small quantity of an albumen, which differs from white of egg, inasmuch as it does not coagulate on boiling, thus possessing a nature more like albumose. The presence of this albumose-like material is very likely the true explanation of the casein in milk not being precipitated by boiling, just as in Sanose it is the albumose which prevents this.

To this explanation we may add that Kirchner attributed to the small quantity of peptone in milk the easy digestibility of that fluid. The greater digestibility of some milks is also known to be due to the finer aggregation of the casein flocks, as shown by comparison of human milk and cow's milk.

This similarity of Sanose to milk, and especially to human milk, gives it a peculiar value, for, as a matter of fact, when Sanose is mixed with water a milk-like liquid is formed.

Sanose is a white powder, odourless and tasteless, forming an emulsion when stirred with water. It has been administered in the following forms:—In milk and cocoa (about one to two ounces in a pint of milk) in pea soup (about one-sixth of an ounce to a plateful), and with soup powder. In none of these forms is Sanose observable to the palate, and it may, therefore, be taken by patients for a prolonged period without objection. Influenced by the opinion that a pure albuminoid diet does not satisfy all the requirements of a sick organism, the writers say they have sought to combine Sanose with other foods of easily-digested character. Thus to one patient they gave Sanose mixed with lævulose, but this mixture proved rather too sweet. A mixture of Sanose with maltose, isomaltose, and dextrine, proved very appetising, and it is thought possible that by combining these easily-digested carbohydrates with Sanose and an easily digested fat in a gelatine capsule, all the necessary food-stuff may be supplied. Experiments are being made in this direction.

For ordinary household purposes Sanose is suitable as an albumen preparation for addition to all foods prepared with flour or meal. Further, it may be added to bread to increase the albuminoid contents. A very tasty bread was obtained with 10 per cent. Sanose, and having a total albuminoid contents of 20 to 30 per cent. For patients who object to meat, or to whom its enjoyment is more or less forbidden—as in nephritis, uric acid diathesis, or diabetes—Sanose bread will, it is surmised, prove an agreeable substitute for aleuronate bread.

Being a palatable, easily-absorbed albumen preparation, and possessing the advantage that no flavouring chemicals are added, Sanose would appear to deserve the serious consideration of all medical men.

Its development will doubtless be watched by them with much interest, and we hope to be able to report progress from time to time concerning it. We understand, *en passant*, that *The Therapist* for the current month contains a valuable contribution to the literature accessible upon the subject, and to its pages we would refer all who are anxious for further enlightenment upon the result of Schering's ingenuity and research.

THE PURIFICATION OF FEED-WATER.

Among the papers presented at the convention of the American Society of Mechanical Engineers at New York, and forming a portion of the "Transactions" (December, 1897), one by Howard Stillman, upon a water-purifying plant, elicited much discussion, and demonstrated that the evils of boiler scale are appreciated by many steam users and engineers.

The plant described by Mr. Stillman is one installed by the Southern Pacific Railway Company at Port Los Angeles, California, for the purification of feed-water to be used by the locomotives on that division. The plant is of interest because of the bad quality of the water treated, there being a large proportion both of carbonate and sulphate of lime and magnesia present, and also because it is a practical working installation in constant and continuous service, about which definite and trustworthy data are available.

The method employed consists of a double treatment of the water, with cream of lime and with carbonate of soda, the reagents being added successively in order to obviate the direct formation of carbonate of lime, which would otherwise occur by the combination of the two reagents with each other. The exact treatment of the water is determined by chemical analysis, after which the necessary amounts can be weighted out and used for each tank full of water. Two purifying tanks are used, the lime being added first, and the precipitated carbonates permitted to settle out, after which the liquid is passed to the second tank and the soda added.

The result is the removal of most of the carbonates and the conversion of the sulphate of lime and magnesia into sulphate of soda, the incrustating matter being reduced from nearly 40 grains per gallon to about 10 grains, and in practice the scaling in the boilers being practically stopped.

The question of the real advantage of purifying the water before feeding it into the boiler is one which elicited some discussion in connection with this paper, and, notwithstanding the objections made to "turning the boiler into a chemical laboratory," several engineers asserted that practical experience showed no harm from the addition of the soda directly to the feed-water in the boiler.

The real criticism of the method lies in the fact that it only partially accomplishes the desired result, leaving fully one-fourth of the scale-forming constituents still present, and reducing the quantity of solid matter in solution by only about 20 per cent. While this may be the best that can be done in purifying water in stock for locomotive water stations, as good if not better results can be accomplished by the use of high-temperature heaters and purifiers, precipitating the sulphates by the use of high-pressure steam in a closed heater.

BEDROOM SANITATION.

THE *Ohio Sanitary Bulletin* says: No room in the dwelling exercises a more potent influence for or against health than the bedroom, excepting possibly the kitchen. The bedroom is occupied for eight or nine hours of each twenty four, and during the time when vitality is at the lowest ebb, and injurious influences therefore most potent.

It is customary with some to have a light burning all night in the bedroom. This is usually a lamp or gas light turned low. This adds greatly to the impurities of the atmosphere and necessitates the bringing in of much larger volumes of fresh air, if we are to keep near the standard of purity. The light is also objectionable on account of the eyes, as previously stated, and most persons have a sounder and more refreshing sleep in darkness than in light.

We may say, then, that our bedrooms should be moderately heated, and that opportunity for fresh air should be given, and by open windows, if necessary. It is usually better to do this by lowering the upper sash. In planning the room the position of the windows and bed should be so arranged that window ventilation can be accomplished without exposing the sleeper to direct draughts. We need have no fear of that bugaboo, night air. Night air is just as wholesome as day air, and in cities is apt to be more so, as being not so much exposed to pollution by reason of travel on the streets.

The location of the bedroom should be such as to admit direct sunshine at least a part of each day. There is no more powerful microbe slayer than sunshine, and the more of it and fresh air we can have in our dwelling-houses the less need will there be for the doctor.

The careful housewife will see that her beds and bed clothing are aired each day and frequently hung on lines out of doors to be exposed to the sun. The furniture of a bedroom should be as simple as possible. Rugs, which may be large enough to cover most of the floor, should be used instead of carpets, as being much easier kept clean and free from dust. Heavy curtains, upholstered chairs, and other dust-catching and retaining contrivances, should have no place in a sleeping-room.

All that has been said may be summed up in fresh air, sunlight, and perfect cleanliness.

Institute of Sanitary Engineers

THE first meeting of the year was held on Thursday, January 13th, in the Arbitration Room, 64, Chancery-lane. Mr. George Macadam, of Berwick-on-Tweed, read a paper on "The Sanitary Laws of the Hebrews, viewed in the Present Light of the Nineteenth Century." He said:—

Mr. Chairman and Gentlemen—When asked by your secretary to prepare a paper to be read before the Institute of Sanitary Engineers, I experienced some difficulties: First, in choosing a subject to write about, and, secondly, in writing about the subject chosen. Before despising, however, what may appear feeble and impotent, we should remember that men of science such as Professor Bailey and others tell us of a minute marine insect with microscopic shells, diatomaccæ and others, which, when alive, glow and sparkle on the surface of the sea, and there build their habitation. When they die they sink in vast multitudes and settle in the bottom of the ocean; these are really the atoms of which mountains are formed and vast plains spread out. If, therefore, my humble paper is but one atom towards building up the sanitary world I shall feel content.

I also hope that to-night we will recognise in history that something of a similar process goes on all the world over; that the influences which appear merely transient have not been so, but have reappeared in other forms and places; that the little things which were forgotten have not been obliterated, but instead have only been accumulating and gathering power. So with the sanitary laws of the people we mention to-night, they may have been lying dormant for thousands of years, only to come to light and power with tenfold usefulness.

Before beginning I wish you to understand that I am not of that favoured people—the Jews. I am afraid a Mac would scarcely pass muster in the Hebrew genealogy; nor yet am I advocating any Jewish or other doctrine, but simply endeavouring to draw a comparison with a few of the sanitary laws which existed long before the British Isles were civilised, but now a nation which I think may justly claim to be the missionaries of all sanitary reform. Upwards of three thousand years ago there existed sanitary laws which are well worthy of our attention, and which might be viewed in the present light of all our modern scientific sanitary research.

During the theocracy on the democratic government of the Jewish people as a nation, these laws were imperative, although there is no evidence existing to lead us to suppose that these people knew anything about bacteria or microbes, &c. In this important matter the people could scarcely be expected to be schooled, having just been brought out of Egypt, where they had been in abject slavery for about 400 years, with little facility for research as regards microbes. Rather they were occupied now in search of something more substantial. Yes, they lived on in blissful ignorance as to the sport and havoc this tribe of microbes played with the sons of men, just the same as we have been living in ignorance, until Mark Twain, by the way, in his wonderful book, "More Tramps Abroad," pictures

us but as microbes of a Great Creator ourselves. Yet these people, the Hebrews, had an Infectious Disease Act, coupled with a Notification Act, upon which, I think, we have improved very little.

Their most terrible scourge was leprosy. The laws and regulations relative to this and similar diseases were most stringent, and perhaps more carefully adhered to than our laws for typhus, small-pox, or diphtheria. On the slightest appearance of anything like the above-named disorders, the infected person was to notify the priest, who, by the way, acted as Medical Officer of Health. The regulations for him were most explicit; if the slightest doubt remained as to his diagnosis of the disease, the sufferer was kept for seven days, after which he was again examined. If then the priest considered him according to law not in a contagious condition, he was kept yet another seven days, then pronounced clean, after which both his body and clothing were washed before exposing himself in the camp. One kind of leprosy—Lepro-Mosaica, covering the body with white spots appeared, after it had spread itself all over the infected one—seems to have died and gone back, much like our small-pox, which after the patient had thoroughly recovered was again perfectly healthy. The Egyptian bondage with its studied degradation and privations, and especially the work of the kiln under the Egyptian sun, must have had a frightful tendency to generate this class of disease. Hence one historian, Manetho, asserts that the Egyptians drove out the Israelites as thoroughly infected with leprosy.

It is remarkable that a nation of slaves newly emancipated should have framed a code of laws so entire, laws which if England as a nation had embraced one hundred years, might have prevented many a serious epidemic. Instead of looking upon infectious disease as a scourge sent us from above, we would have found the cause emanating from our filthy houses and surroundings and general uncleanliness.

Let me refer one moment to the state of matters existing prior to the Royal Commission's report in 1838—9, and which was published in 1842. There existed, mark you, certain sanitary laws prior to this time, but the many difficulties in administering the same made them unworkable, but more like what we would call in Scotland, like a when Tata bogles, more like to frighten folks than be of any material use.

I could tell you about houses, from London to Glasgow, the conditions of which were hotbeds for all infectiousd iseases. Cottages below the street level with mud floors. Open ditches running by, and every now and again flooded with filth. Dung heaps and filth accumulation stored for twelve months against the walls of the houses. Fever patients lying dying amongst the living was the general thing at certain seasons of the year. I shall give you two examples (one in Glasgow first): We entered a dirty low passage, like a house door, which led from the street through the first house to a square court immediately behind, which court, with the exception of a narrow path around it, leading to another long passage, through a second house which was occupied entirely as a dung receptacle of the most disgusting kind. Beyond this court the second passage led to a second square court occupied in the same way by its dung-hill, and from this court was a third passage leading to a third court and a third dung heap. There were no privies or drains there, and these dung heaps received all the filth from the swarm of wretched inhabitants, and we learn that a considerable part of the rent of these houses was paid by the produce of the dunghills. Thus, worse off than wild beasts, many of which withdraw to a distance and conceal their ordure. The dwellers of these courts converted their shame into money to pay their lodgings. The state of the open drains was something horrible.

Take Windsor, where rank and wealth resided. From the back of the gas works (in 1842) to the end of George-street a double line of open, deep, black and stagnant ditches extended to Clewer-lane. From these ditches an intolerable stench was perpetually rising and producing fever of a severe character. There were other drains equally bad running from the barracks into the Thames. The contents of these ditches were only carted away when sold as manure. It may seem strange that an existing law, which was read almost daily in our churches, should not have been made applicable to our own country before the latter part of the present century. Yet you will admit that legislative power can only be passed when a country is in some measure prepared for it. One of the most difficult things to attain to is thorough co-operation with the masses of the people to assist the Sanitary Authorities in carrying out these Acts, their officers looked upon as a limb of the law to be dreaded, instead of considering that they are assisting to pay the man whose duty it is to protect their health; and this in the enlightened nineteenth century.

(To be continued.)

General News.

SALTCOATS.—The Commissioners of Saltcoats and Ardrossan have decided to erect a new joint hospital. The site has not yet been fixed.

WORTHING.—The Town Council has resolved to apply to the Local Government Board for sanction to borrow the sum of £2750, the estimated cost of covering in the new reservoir at the waterworks.

KNARESBOROUGH.—The Rural District Council has appointed a deputation to meet a similar one from the Urban District Council with the object of discussing the advisability of providing a joint infectious diseases hospital for the district.

AYR.—A committee of the Public Health Committee has been appointed to take all necessary steps towards the stamping out of the present epidemic of scarlet fever in the town. The authorities are convinced that the fever was caused by contaminated milk. It is of a mild type.

TRURO.—The City Council recently considered a report by Professor Kanthack, which stated that oysters sent to him showed strong evidences of sewage contamination. It was explained that the worst report was on oysters taken from Malpas, whilst those further down the river were given an almost clean bill, and it was resolved to forbid the laying down of oysters at Malpas in future.

MARKET BOSWORTH.—The Council has decided to erect an isolation hospital at Ibstock.

WORCESTER.—A loan for £400 for the purchase of twelve Deacon's waste-water meters has been applied for.

RUGBY.—A report to provide a better water supply, at a cost of £20,000 to £25,000, is under the consideration of the Council.

HEANOR.—The Urban District Council is considering the purchase at a cost of about £600 of a plant in connection with the well-boring.

TUNBRIDGE WELLS.—The Town Council has decided to appoint a temporary Assistant Sanitary Inspector, at a salary of £100 per annum.

HARTLEPOOL.—An outbreak of typhoid fever has broken out at the workhouse, and last week the number of cases had reached seventeen. The entire investigation of the cause is in progress.

HETTON.—The Urban District Council of Hetton-le-Hole has decided to write the Houghton-le-Spring Rural Council drawing attention to the fact that the Council was allowing the water to be polluted at the Dene House Farm.

GLOSSOP.—Owing to the prevalence of scarlet fever in the borough, the Corporation has decided to enlarge its fever hospital by the addition of a new wing, 40ft. by 20ft., at an estimated cost of £200. The new portion will provide for eight more beds, and will be used at first for convalescent patients.

HOLLAND (LINCS.).—The Board of Agriculture has notified the Committee of the Council having the administration of the Contagious Diseases (Animals) Acts that it is not in a position for the present to remove the restrictions. The committee has decided to license the markets at Spalding and Holbeach for the sale of fat swine for slaughter.

BARRY.—The Hospital Committee of the Barry District Council has resolved that a site of not less than five acres shall be obtained for the purposes of a general hospital for Barry, and that an accident ward, with accommodation for twenty-four beds, shall be provided forthwith, this building to be in accordance with a block plan capable of enlargement at any time.

LONDON.—The want has been felt for many years at the Zoological Gardens of an independent water supply, and recently it was decided to put down an artesian bored tube well, the results of which have been, as was anticipated, the tapping of powerful springs of pure water in the chalk at the depth of 450ft., yielding 240,000 gallons per day. The engineers are Messrs. C. Isler and Co., of Southwark.

LEITH.—The deaths registered within the burgh during the year 1897 numbered 1526, giving a death rate of 20·2 per 1000. The deaths in 1896 numbered 1183, and the death-rate was 16 per 1000. Of the total deaths, 183 were due to infectious disease, viz.: Measles, 93; whooping-cough, 68; scarlet fever, 11; typhoid, 4; diphtheria, 4; membranous croup, 1; small-pox, 1; puerperal fever, 1. Of the total deaths, 743 were of children under five years old, and 437 of these were under one year. Under the Notification Act, 644 cases of infectious disease were notified. The births registered numbered 2518, giving a birth-rate of 33·4 per 1000.

SUNDERLAND.—The Council has decided to advertise for an inspector of sewers at a salary of £140, to rise by £10 per annum to a maximum of £180.

EAST MOLESEY.—It appears that the Southwark and Vauxhall Water Company propose to construct two large storage reservoirs, practically covering about 146 acres.

LAMBETH.—A Doulton Institute for the use of the workmen of the firm of Messrs. Doulton and Co., Lambeth, as a memorial to the late Sir Henry Doulton, is to be erected in High-street.

NORTHWOOD.—The Newport Waterworks Committee has decided to acquaint the Rural District Council that the Corporation is prepared to purchase the mains, &c., by agreement or valuation.

WINSFORD.—The Urban District Council at a recent meeting discussed the scheme of the Cheshire County Council for providing a joint infectious hospital for Mid-Cheshire. Most of the members opposed the scheme of the County Authority, and a resolution was passed to the effect that the Council could not see its way to take any immediate steps in the matter, being already possessed of a temporary hospital, which was adequate for present needs.

EDINBURGH.—The Social and Sanitary Society of Edinburgh was to present on the 11th inst. a petition to the Corporation of Edinburgh, the principal clauses of which urge the registration of a separate lodging-house for women only, and the appointment of one or more women as Sanitary Inspectors. At present, although there are forty registered lodging-houses, there is not a single one reserved exclusively for women, and there is no woman Sanitary Inspector.

WHITBY.—The Rural District Council instructed Messrs. D. Balfour and Son, civil engineers, Newcastle, to report on a scheme of water supply for the township of Tylingdales in its district, including Robin Hood's Bay, Thorpe, and Thorpe-lane. The engineers' recommendations, which have been adopted by the Council, are the acquisition of the numerous springs at Spring-hill, and conveying to a collecting chamber, thence the water to be taken in a 5in. main to Park-gate, where it is proposed to construct a service reservoir, with a capacity of 200,000 gallons. The water will then be distributed over the township in cast iron mains, with the necessary valves and other appurtenances.

CAMBORNE.—From Wadebridge the scene of a scourge of typhoid has been shifted to Camborne. Apart from, or rather in addition to, any neglect of sanitary precautions, there has probably been something peculiarly favourable to the germination of typhoid in recent atmospheric conditions. Where there has been anything like pollution of water supply, no doubt the mild season has favoured the outbreak of a typhoid epidemic. It seems to be conceded that one source of the water supply of Camborne and Illogan has become polluted, and that the present very serious epidemic has been the result. The Truro Sanitary Committee has already been led to thoroughly inspect the water supply of the city.

Personal.

MR. A. FRIGELLE has been appointed Vaccination Officer for Dudley.

MR. J. CLOUGH has been appointed Medical Officer for the First District of Hunslet.

MR. WILSON, Chief Constable, has resigned his appointment as Sanitary Inspector for Montrose.

J. R. M. RICHMOND, L.S.A., has been appointed Medical Officer of Health for the rural district of Overton.

W. E. HACKER, M.D., B.S., has been reappointed Medical Officer for the River Tyne Port Sanitary Authority.

T. G. DICKSON, L.R.C.P., L.R.C.S., Edin., has been appointed Medical Officer of Health for the urban district of Hay.

DR. BERNARD DYER has been reappointed Analyst for Cornwall, under the Fertilisers and Feeding Stuffs Act, 1893.

HUGH T. JONES, L.R.C.P., M.R.C.S., has been reappointed Medical Officer of Health for the urban district of Hucknall Torkard.

THE Skipton Urban District Council has increased the salary of its Surveyor, Mr. T. Mallison, by £30 per annum.

DR. HARPER has been appointed by the Joint Hospital Committee, Medical Officer for Clenoch Hospital, during the current year.

MR. ROBERT SQUIRE has been appointed Inspector of Nuisances for the urban district of Ottery, at a salary of £30 per annum.

DR. WALKER has been reappointed Medical Officer of Health for the Rural District of Stoke-on-Trent, at a salary of £55 per annum.

MR. H. BOTTOMLEY has been reappointed Surveyor, and Dr. Macgregor Medical Officer, for the outer district of Bingley, for the ensuing twelve months.

MISS ALICE BILLINGS, of Forest Gate, has been appointed Lady Sanitary Inspector under the West Ham Town Council, at a commencing salary of £80 per annum.

MR. DAVID BALFOUR, M. Inst. C.E., F.G.S., 3, St. Nicholas'-buildings, Newcastle-on-Tyne, has taken into partnership his son, Mr. David Balfour, jun., Assoc. M. Inst. C.E., and the business in future will be carried on under the name of D. Balfour and Son.

MR. THOMAS M. DRAPER has been appointed Inspector of Drainage Works for new buildings under the Withington Urban District Council. On leaving the Manchester Sanitary Department his late colleagues presented him with a valuable collection of scientific books. Chief Inspector Stansfield, who made the presentation, observed that Mr. Draper had held the position he was leaving for upwards of ten years. The books he had the pleasure of presenting would be of essential service to him in his new duties, but it was not merely their intrinsic value that he would esteem, but more especially the good-will of his fellow inspectors, of which the gift would be an abiding memento. They all agreed in wishing him success in his new appointment.

DR. FRASER has been reappointed Medica. Officer for Colwyn Bay.

MR. C. R. H. CRAWFORD has been appointed Medical Officer for the Fifth District of Tonbridge.

R. LLEWELYN JONES., M.B., L.R.C.P., has been appointed Medical Officer to the Durham County Asylum.

THE Town Council of Nelson has increased the salary of Mr. C. T. Copley, its Assistant Surveyor, by £25 per annum.

MR. J. M. S. PRESTON has been appointed Assistant Medical Officer of the New Bridge-street Workhouse, Manchester.

THE Local Government Board has sanctioned the appointment of Dr. Knapp, as Medical Officer for the Rural District of Ross, at a salary of £60 per annum.

Sewerage Schemes.

[To MUNICIPAL ENGINEERS AND SURVEYORS.—The Editor will be pleased to receive items for publication relating to sewerage schemes projected or inaugurated, together with explanatory diagrams or photographs. The former should be drawn and lettered in black ink.]

A LOCAL Government Board inquiry has been held at Ffynnongroew into a complaint of the default of the Holywell Rural Council in not providing sewers adequate for the locality.

A LOCAL Government Board inquiry was held at Marlborough on Friday, the 14th inst., into an application of the Town Council for sanction to borrow £6800 for the purpose of sewerage and sewage disposal.

A LOCAL Government Board inquiry has been held at Ramsbottom into the Council's application for sanction to borrow £15,000 for sewerage works, and £5,000 for street improvements. The Inspector adversely criticised the Council's action in proceeding with the sewerage plan at Lower Summerseat without the Board's sanction. The Council's explanation was that infectious diseases had broken out there.

THE Local Government Board has written the Coalville Urban District Council suggesting that owing to the opposition offered at the recent inquiry of the sewerage scheme to the site selected for the disposal of sewage from the Whitwick Ward owing to its close proximity to the populated portion of the parish of Thringstone, the sewage from the part of the district in question should be pumped to the site at Kelham Bridge. If, however, the District Council considered more than two outfall sites were necessary or desirable, the Local Government Board requested that the site selected for the treatment of the sewage for the area in question should be quite away from the immediate neighbourhood of the village of Thringstone. The Council has resolved that Mr. Everard prepare amended plans and rough estimates with respect to the Whitwick portion of the scheme, and consult the Sewage Committee after seeing the inspector (Major Tullock) thereon.

A LOCAL Government Board inquiry has been held at Skircoat with regard to an application by the Halifax Rural District Council for power to purchase a site for the treatment of the sewage of the parish of Skircoat.

A LOCAL Government Board inquiry has been held at Rhymney into an application by the Urban District Council for power to borrow a sum of £10,000 for the purpose of carrying out a system of sewerage and sewage works for the district.

IN consequence of an unfavourable report upon the working of the sewage purification works of the Cleckheaton District Council in the Scholes Ward, the General Purposes Committee has decided to instruct Mr. Woodhead, C.E., of Bradford, to report upon the works. The system is that of irrigation.

AT a recent meeting of the Perthshire County Council a long letter was read from the Clerk of the Comrie Parish Council, enclosing supplementary report and plan by Mr. Copland, C.E., Glasgow, anent Comrie drainage, and asking the District Committee to contribute a proportion of the cost in respect of the surface water off the roads going into the drains. Under the new drainage scheme the cost is estimated at £1150, as against £3300 as at first proposed. The Council has not yet decided the matter.

AT a special meeting of the Morecambe District Council on the 14th inst., the twelve competitive schemes for the sewerage of the district were again considered, and eventually one submitted by "Forward" was adopted. This scheme will serve for a population of 60,000, including Bare and Torrisholme. The estimated cost of the works is £39,227 10s. 9d. (exclusive of way leaves, engineering, or land), with an estimated annual working expenditure of £620 2s. 6d., for a population of 45,000. To this must be added the cost of the "septic system," which has already been agreed to, and which will form a part of the scheme. The successful competitor is Mr. H. B. Nichol, C.E., of Birmingham.

WITH reference to the disposal of Thorne sewage, the four representative members of the District Council recently presented a report to be forwarded to the Clerk of the County Council. They point out that the main sewer, the "Boating dyke," is 1¼ miles in length, upwards of ½-mile, passing through the principal portion of the town, is arched over, and as to the open part, less than a dozen cottages adjoin it. The main sewer is regularly cleansed under the supervision of the Sanitary Surveyor, and has the advantage of being flushed from the upper end throughout the entire length by water from the canal. The sewage is carried by means of a land drain to Keadby, where it is discharged into the Trent. Dr. Arbuckle agreed that it was unnecessary to adopt a modern scheme for treating crude sewage, which in a district so low-lying as Thorne, would be very expensive. He had not been able to trace any definite sickness to the open sewer. The report was unanimously adopted and ordered to be sent to the County Council.

THE Harrogate Corporation has decided to work the pumps at the sewage farm, Ripon-road, by an electric motor in place of a gas engine.

A COMMENCEMENT has been made with the drainage of the eastern section of Newburgh, Mr. Stevens, the contractor, having placed a strong staff of men on the works. This contractor is also the lowest offerer for the Lochmill water scheme, which, it is expected, will be shortly put in hand.

AT a recent meeting of the Truro City Council the Sub-committee appointed to inspect Colonel Ducat's aërated bacterial self-acting filter for sewage purification at Hendon reported that they were of opinion that the filter was a further advance in the natural treatment of sewage, but the filter at Hendon was of such an experimental nature that they were unable to say whether it would carry out all that its authors professed, and, therefore, they awaited a further extension of the system with great interest.

AT the last monthly meeting of the Somerset Drainage Commission a deputation from the Langport Rural District Council presented a plan for the carrying of the sewage of Langport into the river Parret, which plan had received the approval of the Local Government Board, and to which the sanction of the Commissioners was asked. After considerable discussion the Commissioners decided not to give any answer in the case until the appeal against the judgment in the case against the Bridgwater Corporation had been decided.

A DEPUTATION from the Neath and Glyncorrwy District Councils recently waited upon the Local Government Board in reference to the direction given by the Board to carry out an elaborate and costly system of drainage for the Afan Valley. The circumstances of the case were fully explained, and the deputation were told that the Board would not insist upon a scheme being adopted by which the sewage should be carried to the sea, and that, possibly, the adoption of septic tanks or Ducat's sanitary system would meet the case. A Local Government Board Inspector would visit the district shortly and report.

SINCE the Alloa Burgh Commissioners purchased from Lord Mar his lordship's rights over the town's water supply, Gartmorn Dam, and also enlarged and improved the then existing waterworks at a cost of about £30,000, a coal pit has been opened in the vicinity of the dam, and the sewage from the mine has been allowed to pass into the loch after undergoing a process of settling in a large tank constructed for the purpose. Quite recently complaints have been made that the sewage pumped up from the pit and conducted to the dam was far from being free from pollution after leaving the settling tank, and the Burgh Commissioners have taken up the matter with the view of ascertaining whether the complaints are well founded, and, if so, taking the necessary steps to put a stop to the pollution. They have agreed that the Water Committee be asked to obtain an estimate of the cost of laying a sewage pipe from Sheriffyards Pit to the Brothie Burn.

THE Clerk to the Cheshire County Council has received an important Local Government Board communication in reference to a recent inquiry at Chester into an application for a Provisional Order constituting a Joint Committee to put into operation the Rivers Pollution Prevention Act in the basin of the river Dee. Opposition was forthcoming from the County Councils of Shropshire, Merionethshire, Denbighshire, and Flintshire. Whilst the Board is of opinion that the constitution of a Joint Committee is the best means of dealing with the situation, it is not willing on the evidence before it to issue such a Provisional Order as that applied for, and it suggests a further conference between the Councils interested.

THE Local Government Board inquiry was continued at Oakengates on the 19th inst. to take evidence in opposition to the order of the Shropshire County Council to form an Urban Council for the district of Oakengates. The Clerk to the Wellington Rural District Council said that body was quite competent to deal with the needs of the district, and had schemes in hand to provide for an adequate water supply to the district, and proper drainage. It was contended on behalf of the Wombridge Parish Council that an injustice would be done to it if included in the proposed urban district, inasmuch as it, while already being provided with a satisfactory system of sewerage, would be called upon to contribute towards a sewerage scheme for St. George's and other parts of the district at present without one. The inquiry was again adjourned.

Lighting.

THE Ossett Town Council has resolved to ask the Gas Company to reduce the price of gas from 2s. 9d. to the former price of 2s. 6d. per 1000 cubic feet.

A LOCAL Government Board inquiry has been held at Stratford Town Hall into the application of the West Ham District Council for sanction to borrow £11,573 for street improvements, electric lighting, and the erection of baths and washhouses.

THE Electricity Committee of the St. Pancras Vestry has decided that the electric light be extended to the whole of the Highgate part of St. Pancras, and the necessary work in connection therewith be carried out at an estimated expenditure of £7585.

THE City Council of Sheffield has decided to negotiate for the purchase of the Sheffield Electric Light and Power Company's undertaking on the terms of £220 of the Corporation 2½ per cent. Redeemable Stock for every £100 of the sum properly expended by the company upon their undertaking, and chargeable to capital account, providing that the amount of such capital expenditure shall not in any event exceed £112,000, any further expenditure properly made being repaid to the company, with 5 per cent. interest.

A LOCAL Government Board inquiry has been held at Longton into an application of the Corporation to borrow a sum of £20,000 for gasworks purposes.

THE Clerk to the Troon Commissioners has been instructed to apply to the Sheriff for powers to carry into effect the resolution adopting the Gas Supply Act.

IT is proposed to light Crieff with electricity through the aid of water power. The amount of capital required is said to be £8000, but the working expenses per year will be much under £1400.

A LOCAL Government Board inquiry has been held at Bexhill to investigate the application of the Urban District Council for a loan of £20,000 for the purpose of supplying electric light to the town.

THE members of the Elland District Council have under consideration the advisability of providing the town with electric light. It is expected if a scheme is to be adopted that one similar to that which is in operation at Nelson will be recommended.

AT a recent meeting of the Boston Town Council a resolution in favour of lighting the town by electricity was carried unanimously, and a strong feeling was expressed that in November next a Provisional Order should be applied for. The cost was estimated at £20,000, and it was contended that, including a sinking fund, the system could be adopted for £800 per year, against £956 now paid for gas.

THE Marylebone Vestry is anticipating erecting a dust destructor to be worked in connection with an electric light station, for which it has already applied for a Provisional Order. At a recent meeting it was agreed that the question be referred to a special committee, consisting of the chairman and one member of the Works, Sanitary and Sewers, and Electric Lighting Committees, to consider and report as to the amount of land required, and the position thereof, for the purposes of a dust destructor, electric lighting station, and other purposes, and that the Vestry Clerk be instructed to write to Lord Portman asking him if he can sell land, and on what terms.

ON Thursday, the 13th inst., an important conference took place at the Municipal Offices, Liverpool, between the Tramways and Lighting Committees. The conference considered a series of proposals made by Mr. A. B. Holmes, Electrical Engineer of the Corporation, outlining an important scheme for extending the electric supply, with the view, not only to meeting the electric tram service, but of lighting the cars, extending electrical street lighting, and supplying electrical energy to users of machinery. The proposals included the establishment of a large new electric generating station on a site near the Leeds and Liverpool Canal, the outlay estimated at £150,000. Eventually the proposals were referred to Dr. Hopkinson, who was asked to report upon them.

A SUB-COMMITTEE of the Aberdeen Town Council recommends that the present lamps in front of the Municipal Buildings and in Castle-street be fitted with the electric light.

THE proprietor of Fort William Gasworks, Mr. Hugh Mayberry, Glasgow, has intimated that the gasworks will be discontinued at the end of this month. In consequence of the stoppage Fort William will now depend entirely on electric light for illuminating purposes.

THE Town Council of Leith has accepted, at £8844, the tender of the India-rubber and Gutta-percha Company, of Silvertown, London, E., for the supply and erection of steam dynamos and accessories, switchboard and storage batteries, required in connection with the electric lighting scheme.

THE members of the Electric Light Committee of the Whitechapel District Board of Works paid a visit a few days ago to Brighton for the purpose of inspecting the electric light installation in that town. They were entertained by Mr. J. Harris, C.C., J.P., the chairman of the Board, and Mr. Morris Abrahams, L.C.C.

AN inquiry is about to be held by the Local Government Board to consider an application by the Barking (Essex) District Council to borrow sufficient money to enable them to lay down an electric light installation for the purpose of lighting the town with electricity. Although Barking is only eight miles from the General Post-office, it has a population of 20,000, and contains, in addition to a local gasworks, Beckton Gasworks—the largest in the world—the town has been lighted with oil lamps ever since 1875, when, owing to a dispute with the gas company as to price of gas, the supply was cut off, and the town has ever since been lighted with oil.

Correspondence.

THE SANITATION OF COWSHEDS, DAIRIES AND MILKSHOPS.

(*To the Editor of* THE SANITARY RECORD.)

SIR,—In an article on this subject by Dr. Kaye, published in your issue of the 14th instant, he suggests that as an aid to effecting necessary reforms in cowsheds "the official undertaking this work should be prepared with a sketch," and he gives a sketch which any person could have drafted from information derived from any one of half a dozen cheap text-books. I suppose "the official" means the Inspector, it can mean no one else.

For although Public Health law gives to the Medical Officer of Health, specially and generally, all the administrative powers of an Inspector, the profession has long ago succeeded in emancipating its members from all the uncongenial duties they are liable to be called upon to perform in respect of procedure against individuals, which ought to be left to a "well-trained Inspector" (*vide* a well-known handbook by a rural Medical Officer of Health, and another by a metropolitan professor to much the same effect). We Inspectors have had enough and to spare of advice by practically irresponsible advisers of what ought to be done. We are, or, rather, we should be if we were not careful, the catspaws, or scapegoats, or both, of a system of administration of the law by local option—a system in which every one concerned has an interest in exerting authority without incurring responsibilty. The legislation by which alone Dr. Kaye's proposed reforms are to be effected, if effected at all, is a farce; for it seeks to put on the "occupier," often a yearly tenant, the onus of effecting structural improvements that ought to be executed by the owner.

It would not make much difference if this were altered. Any active and conscientious Inspector who should manage by any means to induce his Board to support him in carrying out the law would simply be preparing a rod for his own back. The Board would be turned out at the next election, and the "official" after them. Any amount of nicely-executed sketches will not save him.

If the public desire such protection as the law in its present condition would afford them they must protect the administrators by securing to them reasonable security of tenure of office which we have been long fighting for. Imperial interests cannot be wholly left to elected Boards; the local option system is a failure, especially in rural districts. It will be said that public opinion will not stand it. Be it so; then the public cannot have the protection of the law. The community cannot have both the enjoyment of a degree of liberty amounting to licence and the benefits flowing from the exercise of well-regulated authority.

If Medical Officers are really in earnest, why do they not practise as well as preach? They have the power—never used—of reporting John Brown or Peter Jones for a specific contravention of a given law, but they will neither lead nor follow nor stand out of the way, confining themselves, as in the article under notice, to educating "the people" to demand of us that which they well know we cannot perform.

It seems a bold thing to say that one great factor militating against sanitary reforms arises from the attitude of the profession by which such reforms are most advocated, but everyone conversant with the minor working of the public health service knows it to be true, and it is a fact that can be proved to the hilt from the writings of the leaders of the profession.

The root of all sanitary reforms is first protection for the Inspector; secondly, that the Medical Officer must either practise that which he preaches or be formally divested of all control of administrative work which has to be carried out on the Inspector's responsibility—work in which the Medical Officer of Health takes no part. No "official" can unite the functions of a missionary and a commercial traveller with those of an administrator holding a certain degree of authority—the one destroys the other. BALAAM'S ASS.

CAMBORNE.—The Medical Officer of Health has reported an outbreak of typhoid fever in this district.

Notes and Queries.

[Subscribers have the privilege of obtaining advice in this column on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed to THE EDITOR, "Notes and Queries," THE SANITARY RECORD, 5, Fetter-lane, London, E.C.]

NOTE.—If an answer be required immediately, a stamped addressed envelope must be enclosed, when we will endeavour to furnish a copy of the answer by post, as owing to the large number of queries received we cannot guarantee the insertion of a reply in the succeeding issue.

936.—ALCOHOL: ITS USE AND ABUSE: BOOKS ON.—"R. W. K." writes:—"With reference to Query 918, your correspondent would find the following books on alcohol and the temperance question 'up to date,' viz.:—(1) 'The Scientific Temperance Handbook,' by Professor Cheshire, F.C.S., &c., price 3s.; (2) 'The Truth about Intoxicating Drinks,' by E. R. Barrett, B.A., price 2s. 6d.; (3) 'The Case for Total Abstinence,' by W. J. Lacey, price 3s. 6d. The above three books are all prize works, and are bound alike as a set. (4) 'Alcohol and Public Health,' by J. James Ridge, M.D., M.O.H., price 2s."

Answer.—We are extremely obliged to our correspondent for the information, which, we have no doubt, will be most useful to our correspondent. The books may be obtained from the Sanitary Publishing Company on receipt of the published price.

937.—HYDRAULIC MEAN DEPTH IN CIRCULAR SEWERS: HOW TO DETERMINE.—"E. H. Q." writes:—"I should be obliged if you would enlighten me as to how the hydraulic mean depth in circular sewers is always $\frac{1}{4}$th $\left(\frac{D}{4}\right)$ the diameter when the sewer is running either full or half full. I have carefully followed 'Notes and Queries' on this subject, but cannot arrive at a satisfactory result. For instance, my working out of the H. M. D. of a sewer 2ft. in diameter is thus:—

$$\text{H. M. D.} = \frac{\text{Sectional area}}{\text{Wetted permeter}} = \frac{\text{Area of circle}}{\text{Length of circumference}} = \frac{D \times D \times \cdot 7854}{D \times 3 \cdot 1416} = \frac{2 \times 2 \times \cdot 7854}{2 \times 3 \cdot 1416} = \frac{2 \times \cdot 7854}{3 \cdot 1416} =$$

$\frac{1}{2}$ diameter, *i.e.*, $\frac{D}{2}$."

Answer.—We described in our answer to Query No. 878, in our issue of November 26th last, how to obtain the hydraulic mean depth, the rule as to which is:—Divide the sectional area of the stream by the wetted perimeter. As we have also pointed out previously, the hydraulic mean depth of circular sewers when running full or half full is $\frac{1}{4}$th the diameter. For brevity we take up our correspondent's working as follows:—

$$\frac{2 \times \cdot 7854}{3 \cdot 1416} = \cdot 5\text{ft., and } \frac{\cdot 5\text{ft.}}{2 \cdot 0\text{ft.}} = \frac{1}{4}$$

the diameter of a 2ft. sewer.

938.—DRAINAGE OF HOUSE: POWER TO REQUIRE DIVERSION OF DRAIN.—"M. S." writes:—"The drain from one house in my district runs under the dwelling and joins the sewer in the front street. I find it defective, as the sewage leaks into the cellar of adjoining property. There is a public sewer at the back, and the drain could be diverted into this. Have the Sanitary Authority power to order the owner to divert it into this, and thus abate the nuisance?"

Answer.—If the existing drain is insufficient in itself, by reason of defective construction, the Local Authority, if satisfied of its insufficiency, may require the owner, under Sec. 23 of the Public Health Act, 1875, to provide a sufficient drain to empty into any sewer which the Local Authority are entitled to use, and which is not more than 100ft. from the site of such house. In this case the Local Authority may require the drain to be connected to the public sewer at the back of the property.

939.—HOUSE DRAINAGE: LOCAL AUTHORITY TO DETERMINE QUALITY OF MATERIALS.—"M. S." writes:—"In this district the Model Bye-laws as to New Buildings are in force, but there are many old houses where the lead waste pipe from the sinks has a 'bell' or a 'D' trap. If I find these defective can I in serving notice on the owner require him to use a proper stoneware gully, or is he at liberty to use what kind of gully he likes?"

Answer.—This is not a case where the Model Bye-laws as to New Buildings apply, but one of defective drainage, proceedings as to which may be taken under Sec. 23 or Secs. 91 to 96 of the Public Health Act, 1875. If the drainage is insufficient by reason of the waste pipe from sink being improperly trapped and disconnected, the Local Authority may serve a notice under Sec. 23 of the Public Health Act, 1875, to provide a sufficient drain. They should describe the materials to be used, and the Local Authority have the exclusive power of deciding whether their directions are complied with in regard to the materials to be used. In Austin *v.* The Vestry of Lambeth, 4 Jur. (N. S.) 274, the Vestry ordered a drain to be made with pipes of stoneware of the best kind and quality, and the builder laid down Aylesford pipes, but the Vestry declared that these were not stoneware, and proceeded to remove them. Stuart, V.C., held that it was for the Local Authority to determine the question, and refused to grant an injunction against them on motion, and this decision was confirmed on appeal.

940.—EXAMINATIONS FOR LOCAL SURVEYORS: HOW HELD.—"R. E." writes:—"Would you please let me know whether there are now any examinations held for Local Surveyors, also the fees for such?"

Answer.—Examinations for Local Surveyors were formerly held by the Sanitary Institute, but these have been discontinued. The Incorporated Association of Municipal and County Engineers, however, now hold examinations for Local Surveyors, the secretary of the Association being Mr. Thomas Cole, 11, Victoria-street, Westminster, S.W., from whom a copy of the syllabus may be obtained. The fee for the examination is three guineas.

941.—LEAD CISTERN: LEAKAGE FROM: PRESERVATIVE FOR CISTERN.—"A Subscriber" writes:—"Could you tell me of any substance or composition with which to coat a lead storage cistern to prevent leakage? The cistern is fixed on the joists of the roof, and it cannot be got down or another cistern put up without taking down the gable end. Curiously, the water is of a very hard nature, but still it affects the lead. The water is not used for drinking purposes. Could you tell me of any composition to stop the action of the water?"

Answer.—It would have been useful to have been furnished with more detailed information than that supplied, in order that we might advise definitely. Is the cistern a lead-lined wooden cistern, and, if so, where and how does leakage take place? Does it come through the face of the sheet lead, or does it arise from the defective jointing or construction of the cistern? It is possible that it may arise from the lead having decayed, but we think it is much more likely to be due to other causes, as to which careful examination should be made, and if our correspondent is still in difficulties, if he will further communicate with us, we will endeavour to advise him.

We gather that the cistern rests on the ceiling joists. But it is incorrect to say that "the cistern cannot be got down, or another cistern put up, without taking down the gable end." If there is access, and room for the plumber to work in the ceiling, the old cistern may be removed and a new one erected, the woodwork for the new cistern being put together in the ceiling, and afterwards lined with lead. We are unable to determine what is meant by hard water affecting the lead. Does the hardness arise from carbonates of lime or magnesia, or from a sulphate, chloride, or nitrate of lime or magnesia? The lead may be coated as a preservative with (1) Torbay or other oxide of iron paint in three coats; or (2) coal tar, boiled till the watery vapour and naphtha are expelled, and mixed when cold with half a pint of naphtha, and the same of boiled oil, to each gallon of tar.

942.—Book on Sanitary Law for Surveyors' Examinations.—"T. H. Q." writes:—"Will you kindly inform me which book you consider the best for rapidly acquiring a knowledge of the Public Health Acts for a candidate preparing for the examination of the Municipal and County Engineers' Association, viz., (1) Stratton's 'Public Health Acts,' or (2) Angell and Morley's 'Guide to Sanitary Legislation'?"

Answer.—For the special purpose required, we are of opinion that Angell and Morley's "Practical Guide to Sanitary Legislation," price 12s., will be found to be much more serviceable than an unannotated edition of the Acts, such as Stratton's "Public Health Acts." In the former the sections applicable to the duties of the surveyor are selected and annotated for him. The book may be obtained from the Sanitary Publishing Company.

943.—Factory and Workshop Acts: Limitation of Time for Proceedings.—"K. U. H." writes:—"Will you kindly answer me the following questions:—(1) What would be the limit of time for instituting proceedings under the Shop Hours Act, 1892? See Sec. 7 and also Secs. 89 to 91 of the Factory and Workshops Act, 1878. (2) Could a person aggrieved under the Act, *i.e.*, a young person or his father, institute proceedings against an employer for an infringement of the Act, without the intervention of the Local Authority or their Inspector?"

Answer.—(1) Summary proceedings for offences and fines under the principal Act (*i.e.*, the Factory and Workshop Act, 1878), as amended by any subsequent Act, are limited by Sec. 29 of the Factory and Workshop Act, 1891 (which is substituted for Sub-section 1 of Sec. 91 of the Act of 1878), to the information being laid within three months after the date at which the offence comes to the knowledge of a Factory Inspector, or, in case of an inquest being held in relation to the offence, then within two months after the conclusion of the inquest, so, however, that it shall not be laid after the expiration of six months from the commission of the offence. (2) We do not think so.

944.—Book of Tables for Plumbers.—"W. W." writes:—"Could you please tell me the full title and price of a book of tables for plumbers, joiners, &c., by Wright or Clarke?"

Answer.—The book required by our correspondent is, no doubt, Clarke's "Pocket-book for Plumbers, Architects, and Sanitary Engineers:" being a collection of tables and memoranda compiled by J. Wright Clarke, price 2s., and obtainable from the Sanitary Publishing Company post free on receipt of the published price.

945.—Inspector of Nuisances: Variation in Terms of Appointment: Advertisement.—"U. D. C." writes:—"Is it necessary for the Urban District Council to advertise in the local papers when they (1) increase the salary of their Inspector of Nuisances, part of whose salary is repaid by the County Council, or (2) if they make the appointment for five or any other number of years, and also increase the salary?"

Answer.—(1) and (2) An advertisement in a public newspaper is not now requisite under the circumstances.

946.—Municipal and County Engineers' Examinations: Books to Study.—"P. S." writes:—"Will you please say what books you recommend to be studied by a person wishing to pass the examination of the Municipal and County Engineers' Association?"

Answer.—If our correspondent will refer to our answer to Query No. 727, in our issue of July 9th last, he will find a list of the books recommended by us to be studied for this examination. Reference should also be made to our reply to Query No. 816, in our issue of October 8th last.

947.—Building Bye-laws: Limitation of Time for Proceedings.—"H. L." writes:—"Some few months ago some additions were made to the rear of a building which contravene Bye-law 54 in respect to the open space required at the rear of a building. No plans have been submitted. Will you please inform me:—(1) What is the time limit in which a Sanitary Authority can take action requiring the removal of such buildings? (2) Does the time commence to run from the time the building was erected or from the date of its discovery by the surveyor? I may add that the building has probably been erected some months, and the contravention consists in having covered a portion of the yard reserved for rear space with a glass roof."

Answer.—(1) and (2) Assuming that the dwelling was erected subsequent to the confirmation of the Building Bye-laws, the addition thereto of the building at the rear will be a continuing offence. In general, an offence against a bye-law must be the subject of summary proceedings within six months after it has been committed. But under Sec. 158 of the Public Health Act, 1875, the existence of the work in such a state as to be in contravention of the Bye-laws is a continuing offence, and in the above case this section seems to apply, so that there is really no limit of time within which proceedings may be taken.

Contracts Open.

The dates given below are the latest up to which tenders can be received.

Shalford (Guildford).—January 24th.—Scavenging.—Mr. Ferdinand Smallpeice, clerk, 138, High-street, Guildford.

Cleethorpes (Grimsby).—January 25th.—Scavenging.—Mr. Egbert Rushton, C.E., surveyor, Poplar-road, Cleethorpes.

Normanton.—January 26th.—Scavenging.—Mr. Eaton, inspector of nuisances, Council Offices, Normanton.

Normanton.—January 26th.—Sewer, &c.—The Urban District Council Offices.

Stockport.—January 26th.—Sewering.—Mr. John Atkinson, A.M.I.C.E., borough surveyor, St. Petersgate, Stockport.

Turton (Lancs).—January 27th.—Sewering, Paving, &c.—Mr. V. W. Laithwaite, surveyor to the Council, Public Offices, Bromley Cross, near Bolton.

Edinburgh.—January 31st.—Sewer.—Burgh Engineer, 1, Parliament-square.

Macclesfield.—January 31st.—Sewers, &c.—Mr. James Thorpe, surveyor, 19, King Edward-street, Macclesfield.

Pontywain (Newport, Mon).—January 31st.—

Drain.—Mr. Thomas Cadogan, 17, Provident-terrace, Pontywain, Newport.

KING'S LYNN.—February 1st.—Sewers.—Mr. E. J. Silcock, C.E , borough engineer, King's Lynn.

LONDON, E.C.—February 1st.—Reconstructing Sewer.—The Engineer's Department, County Hall, Spring-gardens, S.W.

CARLETON AND DARRINGTON (NEAR PONTEFRACT).—February 2nd.—Drainage Works.—Mr. J. Richardson, M.I.C.E., 5, Central Bank-chambers, Leeds.

Vacancies.

ASSISTANT ENGINEER (LONDON, E., January 22nd).—For the Whitechapel Infirmary, Vallance-road. Salary, £35 per annum, to be increased to £40. Application forms may be obtained at the office of Mr. William Vallance, clerk to the Guardians, 74, Vallance-road, Whitechapel, E.

ASSISTANT ENGINEER (January 27th).—Salary £200 per annum, with prospect of increase by increments of £20 per annum to £280. Messrs. Brown, 17, Tothill-street, Westminster.

ASSISTANT GAS ENGINEER (BRADFORD, January 31st).—For the Gas and Electricity Supply Committee. Salary £250 per annum. Mr. George McGuire, town clerk, Town Hall, Bradford.

ENGINEER (LONDON, S.E., January 31st).—For the Brook Fever Hospital, Shooter's Hill, Kent. Wages £3 per week. Forms of application can be obtained at the Chief Office of the Metropolitan Asylums Board, Norfolk House, Norfolk-street, Strand, W.C.

INSPECTOR OF NUISANCES, &c. (KETTON, STAMFORD, January 22nd).—Salary £100 per annum. Mr. R. M. English, 40, Broad-street, Stamford.

WATER INSPECTOR, &c. (JERSEY, January 29th).—For the Jersey New Waterworks Company, Limited. Mr. H. G. Foster Barham, secretary, 27, Broad-street, Jersey.

To Surveyors, Sanitary Inspectors, &c.—First-class Cycles at reasonable prices. Don't place your orders elsewhere until you have seen our post-free catalogue.—MELROSE CYCLE COMPANY, Coventry.

13th January, 1898.

SANITARY INSTITUTE EXAMINATIONS.

TUITION BY CORRESPONDENCE.

An Engineer and Surveyor (Mem. San. Inst.), Certificated Surveyor and Inspector, prepares students for these Exams. by Correspondence through the post.

Fees strictly moderate. Cramming studiously avoided.

The course of tuition is arranged so as not only to qualify the student for passing the exams., but what is of equal importance, viz., that he may become a thoroughly efficient Inspector.

On successfully passing the exams., all possible assistance and advice is given to help forward intending candidates for public offices.

Many of my old pupils are now filling positions with salaries of over £120 a year.

For terms, &c., address "C. E.," care SANITARY RECORD, 5. Fetter-lane, London, E.C.

SANITARY ASSOCIATION OF SCOTLAND.

EXAMINATIONS IN SANITARY SCIENCE.

Examinations for Certificates of Competency in Sanitary Science are held each year as follows, viz.:—In Glasgow in April, in Edinburgh in October, and at such other time and place as the Board of Examiners may determine.

Entrance Fee £2 2s.

For further particulars apply to

GEORGE MIDDLETON, M.A., LL.B.,
Writer, 92, Bath Street, Glasgow,
Secretary to the Board of Examiners.

A Stamped Addressed Envelope must accompany all letters requiring an answer.

PART 1 OF NOTES ON

Practical Sanitary Science.

BY WILLIAM H. MAXWELL,

Author of Drainage Work and Sanitary Fittings, &c.

FORMING A COMPLETE TREATISE UPON

VENTILATING, LIGHTING, & HEATING.

PRESS OPINIONS.

"An entirely useful book, being both lucid and condensed, and the diagrams and illustrations are excellent. It is fully up to date, and well supplied with references, and as a text book is admirably suited to the needs of those for whom it is intended."—*The Hospital.*

"The book will not only be useful to candidates for examination, but also to busy men in practice who desire a summary of the chief points to be observed in carrying out any schemes of ventilation, lighting, and heating . . . the book is well illustrated and clearly printed."—*The Surveyor.*

Now Ready. Price 2s. net. Demy 8vo., Cloth, Gilt, 50 pp. With Numerous Diagrams.

Calculation of Areas, Cubic Space, etc.,

BEING PART II. OF

Notes on Practical Sanitary Science.

BY WILLIAM H. MAXWELL,

Author of Drainage Work & Sanitary Fittings, &c.,

PRESS OPINION.

"The 'Notes' will, we believe, be found to be of use also to engineers and surveyors in practice, being prepared in a concise form and of ready reference. Some of the most important theories as demonstrated in Euclid are given, and a passing reference is made to the use of Trigonometry and Logarithms. The concluding chapter treats of the calculation of quantities of earthwork."—*The Surveyor.*

DRUGS

WON'T DO.

FREE TRIAL OF SOMETHING THAT WILL DO.

You would be perfectly astonished if you were made aware of the many thousands of pounds absolutely thrown away from year to year upon so-called curatives that are foisted upon a public only too willing to believe the specious arguments laid before them.

Now, strength and muscular activity, rosy cheeks, plumpness and health, can be obtained without medicine.

It can be accomplished with a perfect, flesh-forming, palatable, and agreeble Food Beverage.

is such a Food Beverage, possessing, as it does, wonderful nourishing, strengthening, and stimulative powers unsurpassed by any other Food Beverage. Dr. Tibbles' Vi-Cocoa is not a medicine. It does simply what it is claimed to do, and its strengthening powers are being recognised to an extent hitherto unknown in the history of any preparation.

Merit, and merit alone, is what we claim for Dr. Tibbles' Vi-Cocoa, and we are prepared to send to any reader who names this journal (a postcard will do) a dainty sample tin of Dr. Tibbles' Vi-Cocoa free and post paid.

Dr. Tibbles' Vi-Cocoa, 6d., 9d., and 1s. 6d. It can be obtained from all Grocers, Chemists, and Stores, or from Dr. Tibbles' Vi-Cocoa, Limited, 60, 61, and 62, Bunhill Row, London, E.C.

SANITARY PUBLICATIONS.

The following books, which are either published or sold by the Sanitary Publishing Company, Ltd., 5, Fetter Lane, London, E.C., will be forwarded to any part of the United Kingdom post free on receipt of published price. Books marked "net" will be forwarded at published price, plus postage.

THE

Sanitary Record,

JANUARY 28, 1898.

Notes.

A RECENT article by a writer in the *Pall Mall Gazette* describes very vividly what must be a perfectly appalling condition of things in the capital of Bohemia. The city of Prague is very old, it is very picturesque, it is one of the most beautifully situated cities in Europe—but it is also one of the most insanitary and pestilential. Unless the account before us is overdrawn, "insanitary" is hardly the fit word to describe the condition of the place. One is impelled to use much stronger adjectives. Imagine a system of sewers that date back for—we would not care to say how many—generations, utterly rotten, impregnated with the germs of disease, and all emptying their filth and their garbage into a river which, at low water, leaves their pestilential mouths exposed, to contaminate the air. The water of the river is so polluted that, says the writer, with a touch of grim humour, "the public are naïvely advised to use it sparingly as a beverage, and to prefer the supply from the town springs." But he proceeds: "A recent bacteriological examination of Prague springs showed that the water was just as undrinkable as that from the river—contaminated with the disease-spreading percolations through the rotten walls of the old city sewers, and for years consumed without the precaution of filtering having been thought of. Truly, 'water, water everywhere, nor any drop to drink'!"

THE worthy citizens are not blind to the danger of this state of affairs, and would like to provide themselves with an entirely new sewerage system, could they but find the wherewithal to pay for it. However, they have resolved to bestir themselves, and do something, and so they have commissioned an English engineer, Mr. Lindley by name, to prepare plans. Mr. Lindley has now executed his commission, and the plans have been approved of. That is the first step. It is at least something. The future development of the undertaking, and the most difficult part of it, is meanwhile wrapped in the tender veil of futurity. Let us hope that this brave attempt to redeem this historic city, the scene of the labours of John Huss, from the ravages of typhoid, and to place it in line with the modern requirements of sanitation, will meet with the success it deserves. Picturesqueness is all very well, but picturesqueness and typhoid do not go well together. In the nineteenth century, at least, we look for better things.

THE plague-spot of Prague is to be found chiefly in the Jewish quarters. There it is not drains only that are at fault. The houses are old and reek with disease. The very name of sanitation, it would appear, is unknown. For the Jews of continental towns are essentially conservative in their instincts, and are not easily moved by the mushroom-like notions, such as ideas of hygiene, that have sprung up so rapidly in this age of progress and characterise an up-to-date community. Their conservatism is well illustrated in the Jewish cemetery, which has been designated as the oldest graveyard in Europe, where their fathers have slept undisturbed for centuries. It is a sacred tradition with them that the repose of the dead shall never be disturbed by the sacreligious hand of "improvement," and so the tombstones accumulate, crowding upon one another, until they are slowly effaced by the gentle hand of time. But the houses of the Ghetto—the "old-world, sacred, pestilential Ghetto," as the writer calls it—of which Prague is so proud, are not to be suffered to enjoy the same immunity, for the ruthless hand of an "improving" Corporation has undertaken the demolition of many of these ancient hotbeds of

disease. Already about two hundred houses have been razed to the ground, and, given the necessary funds, the day is not far distant when the whole of that home of pestilence will be but a memory of the past.

THE action of the Great Western Railway Company in promoting a line of railway from Marlow to Henley, along the Berkshire side of the Thames, is exciting a good deal of feeling, and it is certain that the Bill will encounter strenuous opposition in the coming session of Parliament. The Thames Conservancy have decided to oppose the Bill resolutely, and they invite the co-operation of the riparian owners and others whose interests are affected. It is said that the line will destroy the beauty of some of the most beautiful river scenery in the kingdom, as well as impair the privacy of the residents. Setting aside the latter objection, which, in a question where the interests of thousands of the masses of the London population are concerned should not be allowed, undue weight, we think that the effect of the proposed line on the scenery has been very much exaggerated. The general manager of the Great Western Railway has pointed out that, as a matter of fact, the line has been specially designed so as to encroach as little as possible on the river scenery. It will be kept well back from the river, and at the points where it crosses at Marlow and below the regatta-course at Henley particular pains will be taken, by the construction of ornamental trellised bridges, not to disfigure the rustic beauty of the stream. And in no way will it interfere with the great annual regatta, its aim rather being to foster and increase it in popularity.

ON the general policy of such an undertaking as this we have frequently expressed our views. The scenery of the Thames is admittedly beautiful. Why then should it be reserved as the exclusive privilege of the favoured few who possess villas on its banks? The spirit of modern democracy recognises that the beauties of our country are the heritage of the people—not to abuse, but to enjoy. They minister at once to the mind and to the body; for in these days of city congestion, and the unhealthy conditions of city life, it is for the public good that the health-giving influences of the country should be accessible to all. And what greater boon could be offered to the toiling masses of London than the opportunity to escape at times from the suffocating atmosphere of fog and smoke to the purifying airs of the upper Thames, their own patrimonial river? The policy of opposition is rooted in selfishness. As a matter of fact, we believe that the results of railway enterprise in other chosen haunts of Nature in this country have belied the fears of pessimistic prophets. Can any one say that the beauties of English lakeland have been impaired, in spite of the preaching of Mr. Ruskin, since the days when Wordsworth sang their praise? Nature is still the same, but she may now be wooed by thousands whose lot is cast in city wall to whom she was previously inaccessible.

ON Saturday last Lord Rosebery opened a People's Palace in the East End of Glasgow, in the very centre of one of the most congested districts of the industrial metropolis of Scotland. In the course of an impressive speech the noble Earl referred to the great growth that had been effected within modern times in the sense of municipal responsibility. Time was when a city corporation confined itself to the purely administrative side of its duties, seasoned by occasional junketings and banquets, on the annual inspection of the waterworks, and so forth. But a more enlightened spirit now prevails, and it is recognised that the municipality is charged with the duty of caring, within certain limits, for the physical and moral welfare of the citizens. Municipal baths, wash-houses, gymnasia, parks, and gardens, are now provided by an enterprising community for the masses within its borders, as well as drainage systems and bodies of police. His lordship also contrasted the position of a Town Councillor with that of a Member of Parliament, and the comparison was not wholly to the advantage of the latter. Unfettered by the gags of party, or the imperious mandates of whips, the Town Councillor can enjoy a feeling of independence and individuality that is denied to the in rank and file Parliament; and the sense of usefulness that is thus engendered gives a dignity to municipal life that is often lacking in the larger and the prouder sphere.

THE eighth annual report of the Vegetarian Federal Union, which was submitted at the annual meeting last week, states that the jubilee of the Vegetarian Society was attained last year, and during the year a Jubilee Fund was inaugurated by the Vegetarian Society and the Vegetarian Federal Union, the funds, amounting to over £1400, being shared equally between the two organisations. By means of this fund a large number of jubilee meetings were held in different parts of the country, besides many meetings, conferences, and functions of a smaller character. A National Congress has been arranged to be held in London from September 11th to 18th, and an International Congress will be held in Paris in September, 1900. Vegetarian literature continues to flourish, and many new restaurants on vegetarian principles have been opened both here and abroad. The president, in moving the adoption of the report, pointed out that in London there were now as many as thirteen different societies, all thriving and growing in strength, most of which had been formed during the past three years. He referred with satisfaction to the fact that the great prejudice with which the movement had to contend at first had practically broken down; it was advancing towards the position which had been attained by the advocates of temperance, and he looked forward with hope to the day when vegetarianism would be recognised not only as a healthy mode of sustenance, but as one of the conditions of a pure and perfect life. But surely, we may be allowed to remark, *en passant*, only a man of extreme views would place vegetarianism and temperance on the same platform.

ONE interesting feature in the discussion was the stress that was laid on the importance of preaching the gospel of vegetarianism by means of practical demonstrations and cookery lectures, and it was stated that there was a growing tendency in the direction of establishing vegetarian cookery centres

in different parts of the metropolis. The average English cook is credited with the smallest possible knowledge of the art of cooking vegetables, the importance of which it is scarcely necessary to emphasise. To remedy this state of ignorance the Federal Union has undertaken to provide competent cooks to impart the needful instruction; the result of their action being that the London County Council has given them the privilege of sending out some of their cooks to give demonstrations in technical cooking classes. One need not be prepared to accept the whole doctrines of vegetarianism to admit that this step should be attended with the most beneficial results, from a health point of view; for the knowledge of how to cook vegetables properly, the chief staples of a healthy diet, is one of the most important branches of culinary education.

THE Mayor of King's Lynn has made an appeal to the public for further subscriptions to the fund for the relief of the poor sufferers from the typhoid epidemic. The calls upon the committee have been so numerous and continuous that, notwithstanding the exercise of the greatest caution and economy, the funds are reduced to a very low ebb. Only £1100 has been subscribed on behalf of nearly 500 cases, mainly among the poorer classes of the inhabitants, and even with the assistance of private charity by the more well-to-do of the citizens, the committee's power to relieve the sufferers has been most limited, and they have been quite unable to deal with the widows and orphans. The expenses of keeping up the Town Hall kitchen, which has been the means of providing thousands of hot dinners to poor patients, and supplying them with the nourishment they so much required, have been very heavy, and there are still numerous cases of great distress, and many convalescents to be helped, for all which money is urgently needed. May we express the hope that this appeal will meet with some response among our readers?

THE Water Committee of the Aberdeen Town Council have discovered a somewhat extraordinary state of matters in connection with an aqueduct leading from one of the city reservoirs. In consequence of a quantity of paraffin having found its way into the water a thorough examination of the aqueduct was made, and this disclosed the fact that the aqueduct was in a very leaky condition. Several cesspools were very near, if not directly above it, and an open drain was found actually to cross the conduit, which is only 2ft. 4in. below the surface. Further, a heap of rotting vegetable matter had been piled above a manhole leading into the aqueduct, while near by was a pit used as a dung receptacle. Not a very healthy state of matters! The Committee, however, put a cheery face on the business, and expect to remedy the mischief by a little judicious patching of the leaks. We trust they will not let the town in for an epidemic. A report on the structure is to be presented shortly to the Town Council by the Borough Surveyor.

TWO cases are reported from the Court of Session in Scotland involving questions of a landlord's responsibility for illness occasioned to the tenant's family by defective drainage in the one instance, and impure water in the other. In the first case the family suffered from typhoid shortly after occupying the house, and when the drains were tested (though that was not till six months after), a hole was discovered in one of the pipes. The tenant removed and sued the landlord for having let him a house that was not in a habitable or sanitary condition. It was pleaded in defence that the drains had been overhauled about eight years before, to the satisfaction of the city engineer, and there was no reason to believe that there was anything wrong with them now. The judge decided that there was no proof of fault except that there was a hole in the drain and there was no proof as to how the hole was made. He did not think a doctor's evidence was enough to prove bad drainage. He therefore gave judgment in favour of the defendant.

The other action was at the instance of Lord Inverclyde, and was an action for rent. In this case, certain members of the family suffered from diphtheritic, sore throat, which was alleged to be due to bad drainage or improper water supply. The water was examined by an analyst, and was condemned. As Lord Inverclyde did not take any steps to remedy the water supply, the tenant left, and declined to pay the rent, putting in a claim for damages. The proprietor said that the lease contained no stipulation regarding the water supply, and disclaimed liability, and the Court upheld his defence. We should have thought that the provision of a proper water supply forms an implied condition in the lease of a dwelling-house, even where there is no express stipulation on the subject. The landlord's obligation is to provide a house that is habitable, and therefore, sanitary; and surely, the condition of the water supply is one of the chief elements in determining whether a house is sanitary or not.

Poisonous Perspiration.—At the French Biological Society, M. Arloing has reported some interesting observations on the toxicity of human perspiration. He found as a result of making intravenous injections of natural perspirations, and also of prepared extracts of the same, that when the strength of the injection approached 15 centimetres per kilogramme in the case of the dog, and 25 centimetres per kilogramme in the case of the rabbit, death almost always occurred, generally within three days, though sometimes not for some weeks, when it followed upon a state of profound cachexia. The injection of one-sixth, one quarter, or one-third of the lethal dose led, according to his observation, to immediate and proportional effects. The toxicity varied with the environment of the subject which furnished the perspiration as well as with the mode of preparation of the extract. The perspiration secreted during arduous muscular toil is richer in toxic principles than that secreted during the ordinary circumstances of life, the degree of extra-malignancy amounting to 25 or 30 per cent. All things being equal, perspirations obtained by artificial means of sudation present a minimum of toxicity; but perspiration obtained from a subject who has suffered from retention of the secretion due to cold, is poisonous.

NOTES ON
PRACTICAL SANITARY SCIENCE.

By WILLIAM H. MAXWELL.

Assistant Engineer and Surveyor, Leyton Urban District Council, Author of "Drainage Work and Sanitary Fittings," "Ventilation, Heating, and Lighting," &c., Certificates of the Association of Municipal and County Engineers, and Sanitary Institute.

No. 46.—REFUSE DESTRUCTORS.

(Continued from page 65.)

Another arrangement of this furnace is shown in Fig. 10.

The *steam jet*, which plays an important part in the Horsfall furnace, forces air into the closed ashpit by means of surface friction at a pressure equal to ½in. of water. This steam, in passing through the glowing carbonaceous cinders, is said to have a "water gas" effect; it "becomes broken up and yields two highly combustible gases, viz, hydrogen and carbonic oxide, and such being afterwards burned in the atmosphere of the cells and in the service and main flues, most materially assist in raising the temperature and in consuming the noxious-smelling gases evolved from the fresh or non-charred town refuse, and aiding in these being changed into innocuous and non-smelling gases."[117] "It is not *claimed* that there is any actual direct gain of heat from the formation and subsequent decomposition of the water gas, but that the action has the effect of carrying the combustion onwards to a further point in the furnace than it would otherwise reach, thus consuming smoke and other combustibles, which would otherwise escape."[118]

As to the special feature in this furnace in the arrangement of the *flues and flue openings*, these, instead of being at the back, as in Fryer's furnace (in which the gases from the drying refuse pass away straight into the main flue) are placed in the front of the reverberatory arch, over the hottest part of the fire. Thus the gases given off by the drying refuse at the back have to pass over the hottest part of the fire (at a temperature claimed to be equal to 2000 deg. Fah.), and through apertures in a red-hot reverberatory arch, before they can escape. The flues pass along over the top of the reverberatory arch, and then down through cavities in the side walls to the main flue underneath. The furnace is therefore practically surrounded with hot gases, which have the effect of drying the green refuse.

In Horsfall's "improved design" a longitudina *trough or hopper* is provided at the back, into which the carts tip direct; but instead of a shoot being provided, as in Mr. Whiley's, to convey the refuse from the hopper to the furnace, the hopper is brought right down to the grate bars, and the opening at the back is made the full width and height of the furnace.

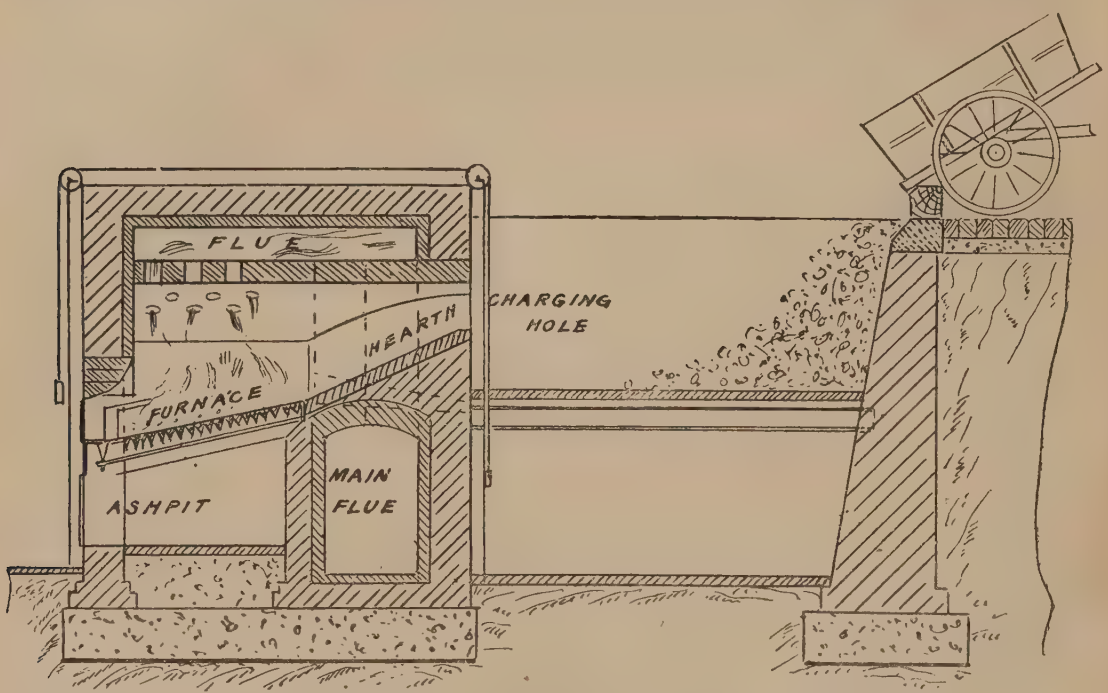

Fig. 10.

The *grate bars* in the improved furnace are Settle's patent,[119] and are of the rocking type without, it is stated, either excessive motion or wide spaces, those bars on to which the refuse first falls being dummies, *i.e.*, without air spaces. The motion is imparted by a small engine, the speed of which can be varied as desired. The *grate surface* proper is 28 square feet in area

[117] *Journal of the Society of Chemical Industry*, March 31st, 1896.

[118] *Health News*, July, 1895.

[119] Patent No. 15,482 (1895).

in each cell. The refuse is gradually moved forwards by a wave-like motion, and deposited in the form of clinker on the wide "dead-plate," where it remains until the attendant comes along to remove it. Thus, it is claimed, the continual admission of cold air to the furnace is avoided, and also less labour is required in raking the clinker off the dead-plate than in shovelling it up off the ground, while all handling of the refuse is obviated until after it has been reduced to clinker. With the use of these bars, it is stated that an output of nine tons per cell per day has been obtained.

There is a separate mattress chamber provided in connection with the main flue, so that large articles can be put into it whole and speedily destroyed.

In the working of the Horsfall destructor, some difficulty is said to arise "owing to the closing up of the comparatively small escape openings leading into the escape service flue, which is due to partial fusion of the brickwork at the high temperature and the adhesion of dust particles to the sides of the openings. The result is the reduction of the openings and draught, and the lessening of the power of the destructor, until the apparatus has been thrown out of work for repairs. Even when working properly, each cell is independent of every other cell, and if any heavy charge of green stuff be thrown in, the temperature of the cell may become materially lowered, so as to admit of foul-smelling gases passing away unconsumed for a time."[120]

The several small escape openings in the reverberatory arch above mentioned are now replaced by the larger opening shown in Fig. 8, which should remove the difficulty referred to.

THE SANITATION OF DOMESTIC BUILDINGS.

By Frank Latham, C.E., M. San. Inst., &c., Assistant Surveyor, Borough of Margate.

CHAPTER II. (*continued*).

Junctions with drains should always be at oblique angles. The Model Bye-Laws of the Local Government Board make a special note on this matter to the effect that "Tributary drains, whether vertical or horizontal, ought always to be formed with proper bends, delivering in the direction of the flow and at the side of the drain into which they discharge." (Fig. 7.)

This is necessary to prevent the interruption of the flow in the drain by a cross current, which would cause a deposit, probably eventuating in a stoppage. (Fig. 8.) In laying drains provisions should be made to give all junctions and bends an extra fall. A tributary drain should always be connected to a junction arm of the same size; thus a 4in. branch drain should not be made to fit into a 6in. junction arm, and so on. All junctions should be made slightly above the level of the invert in the case of house drains, and not, as is sometimes done, brought in at the top. It is often the case that when a drain passes close beside a gully, &c., for the pipes to be brought straight down and the junctions made in the top of the drain. This is a pernicious

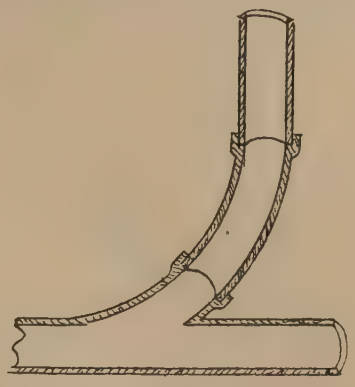

Fig. 7.

practice, and one to be condemned. Slow bends in connection with proper junction pipes should be used.

The junction of house drains with existing sewers should be by proper bends, the same as in the case

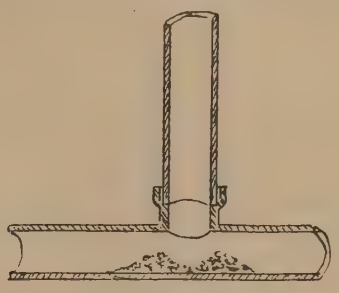

Fig. 8.

of drains and the practice of knocking a hole in the side or top of the sewer, and simply thrusting the end of the house drain into it and making good with cement, should be a thing of the past and aban

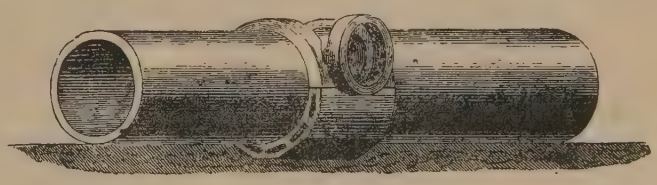

Fig. 9.

Fig. 9.

Fig. 10.

doned for the future. These connections should be executed with saddle pieces. (Figs. 9 and 10.)

Connections with brick sewers should be made

[120] *Journal of the Society of Chemical Industry*, March 31st, 1896.

by means of proper junction blocks specially manufactured for the purpose, care being taken that these are not turned in the wrong direction, as is not infrequently the case. (Figs. 11 and 12.) With existing iron sewers junctions should be made by boring the pipes to the size required,

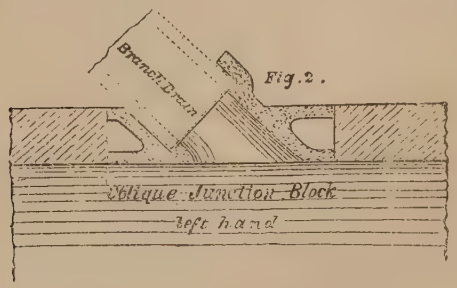

Fig. 11.

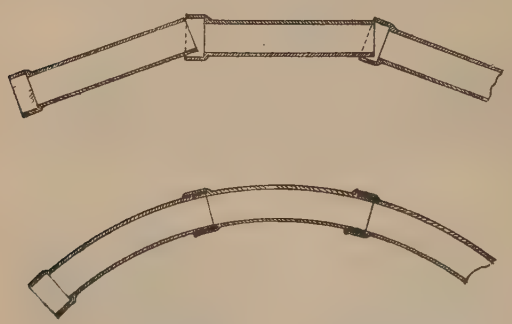
and proper connections made with saddle pieces. When it is necessary to have bends in drains, easy curves should be used, which can always be obtained, made in the same material as the pipes. (Fig. 13.) It is a gross mistake to form curves with straight pipes (Fig. 14) a method which is too often followed by some who know no better. The results in such cases are, that proper joints cannot be made owing to one side of the spigot

Junction Block.

Fig. 12.

being drawn nearly out of its socket in producing the required angle, while the other more or less closes up the cavity required for the cement joint, and thus only the top and bottom of the drain are able to be jointed, while the two sides



Figs. 13 and 14.

are imperfect, and at the same time impeding the flow.

When it is necessary to enlarge small drains in their course, taper pipes should be used, which are made, for instance, with a 4in. socket, and the pipe or barrel gradually enlarged to 6in., and so on, so that a drain can be enlarged at any required point without any unevenness or projection in the interior. The usual form of taper pipe is, however, incorrect; for instance, a taper enlarging a 4in. into a 6in. should be so formed as to bring the top of the 4in. lineable with the top of the 6in. pipe, the development being below the axis of the 4in., thus giving full advantage of the enlargement, otherwise when the 6in. is running full the sewage must back up into the 4in. Taper bends, when required for similar purposes, should also be advocated.

It is not an uncommon practice to make an increasing joint by thrusting the spigot of the smaller pipe into the barrel of the larger one and packing the joint in the ordinary manner between the two. This leaves a ridge or projection of more or less size in the inside of the larger pipe, which is not satisfactory. Another way is by cutting the barrel off within an inch or so of the socket of the smaller pipe and bevelling the inner edge of the spigot thus formed. This is then inserted into the larger pipe, the socket of the smaller one, in certain cases, fitting into the socket of the larger one, leaving just sufficient space between the two to make a joint. This method is a troublesome one, and not to be compared with that of purpose-made taper pipes. When stoneware pipes are required to be cut they should be stood on end and filled with sand, the inertia thus produced reducing the liability of fracturing or cracking the shell.

Sanitary Inspectors' Associations.

SOUTH WALES AND MONMOUTHSHIRE.

THE first annual meeting of the members of the above Association was held at the Town Hall, Newport, on Saturday afternoon, January 22nd, Mr. Edward Walford, M.D., D.P.H., of Cardiff, presiding. There were also present Dr. Herbert Jones, M.O.H., Rhondda, vice-president and hon. treasurer; Dr. Howard Jones, M.O.H., Newport, Mr. J. Towy Thomas, hon. sec. There was a good attendance of the members of the Association, which incidentally during the discussion of the rules was stated to consist of eighty members.

Mr. ROWLANDS, Pontypridd, raised the question of increasing the fee for membership from 5s. to 10s. per member, remarking that he hoped to see some benefit arising from the scope of the Association's operations, and he did not see how much could be done with such a small subscription.

Mr. HERBERT JONES, Rhondda, said he thought if they got no more than eighty members there would, after providing for the cost of printing the quarterly journal, be a small surplus at the end of the year. The rule was then allowed to remain as drafted.

The nominations were then proposed, as honorary members, of Dr. Howard Jones, Medical Officer of Health, Newport; Dr. T. Hall Redwood, Medical Officer of Health, Rhymney; Dr. J. W. Mulligan, Medical Officer of Health, Abersychan; Dr. Howard Davies, Medical Officer of Health, Pontypridd; Dr. George Neale, Medical Officer of Health, Barry; Dr. Edward Treharne, Chairman of the Committee of Health, Barry; and Dr. J. Griffiths Lock, Medical Officer of Health, Tenby.

Mr. A. P. PRESTON, Cardiff, read a letter from

the Sanitary Inspectors' Association with reference to the status and working of that organisation, and proposed a resolution that the secretary write to the London Association asking for a copy of the Sanitary Inspectors' Bill which is about to be brought before Parliament, and that the members of Parliament for South Wales and Monmouthshire be asked to support the same.

Mr. OWEN, Cardiff, thought the meeting should take no notice of the letter, as at Cardiff they were unanimous that the South Wales Association should not be affiliated with the London Association. Ultimately the meeting decided to allow the letter to lie on the table, and Mr. Preston waived the moving of the resolution, which accordingly fell through. The President of the Association, Dr. William Williams, Penarth, who was unavoidably absent, wrote intimating that the presidential address would be delivered at the next meeting, to be held at Swansea in April. Succeeding meetings were fixed at Barry in July and at Merthyr in October.

Mr. SPENCER JONES, Chief Sanitary Inspector, afterwards read a paper on "Meat Inspection," which dealt exhaustively but concisely with the various diseases of animals, and how meat of animals so diseased might be identified. Specimens of "fluke," the hair-like worm in pigs producing trichina, &c., were handed around preserved in bottles. During the past year 2059 lb. of beef, 794 lb. of mutton, and 627 lb. of pork had been condemned in Newport.

The CHAIRMAN, in thanking Mr. Jones for his paper, said meat inspection could hardly be carried on properly in the absence of public slaughter-houses under municipal control. Even then, unless private slaughter-houses were abolished, the difficulty was not overcome. He was rather astonished to find, out of thirty-three large towns to which he had occasion to write for information, that there were only two (Burnley and Cardiff) where private slaughter-houses had been abolished. He thought the proper person to decide on unsound meat was a veterinary surgeon, and he was glad that his own Authority had been able to see their way to the appointment of a veterinary surgeon, whose appointment had been very beneficial.

Mr. W. J. HUGHES (Rhondda) favoured the appointment of Sanitary Inspectors directly under the Government.

Mr. JOHNS (Pontypridd) said the difficulty in his district was that there were many private slaughter-houses which could not be closed without compensation.

Dr. HOWARD JONES said there were ten private slaughter-houses at Newport which it was hoped would be closed on the falling in of leases.

Mr. LEYSHON (Barry) said that in that district "blown" veal was forbidden by a clause in the local Act.

Mr. SPENCER JONES, replying to the vote of thanks, said he hoped that Sanitary Inspectors would study the question of meat disease, and not allow what was a purely sanitary matter to pass into the hands of veterinary Inspectors.

The members of the Association afterwards were entertained to tea by Dr. Williams, the president, who came to the meeting at the close of the proceedings and was heartily welcomed. In reply to Mr. W. Williams (Chepstow), Mr. Vaughan (Cardiff) stated that the matter referred to in Mr. Preston's waived resolution had been under the consideration of the Council and would receive their close consideration. Of course the Council could not have foreseen that the resolution would be dropped.

WOMEN SANITARY INSPECTORS IN GLASGOW.

As the suggestion that women should be appointed as Sanitary Inspectors in Edinburgh has aroused considerable interest, an *Edinburgh Evening News* representative called on Mr. Peter Fyfe, F.R.S.E., at the Sanitary Chambers, Glasgow, for the purpose of ascertaining the actual work done by women in this direction in that city.

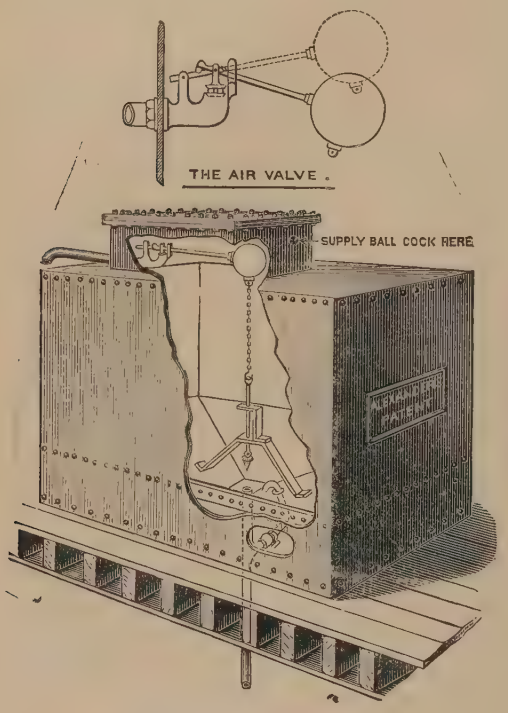
"We have," said the Chief Sanitary Inspector, "six female Inspectors in this department, but they have not the status of Sanitary Inspectors. They were first appointed about twenty-five years ago, and, so far as I know, Glasgow is the only place in Scotland where female Inspectors are employed. The age of our present female Inspectors varies from twenty-eight to fifty-five. When they were first appointed there was no age limit fixed, but we prefer them now to be between twenty-five and thirty-five. Their qualifications for the post are ascertained by an examination which I personally put them through as to their knowledge of domestic hygiene and the health laws applicable to this city and Scotland in general. General education, of course, is an important part. The work they are engaged in is the inspection of houses of the lower-class population. Where the floor, walls, ceilings, &c., are found in a dirty state the occupiers are warned, and if no improvement is found on re-visitation a statutory notice is issued calling upon them to have the work done, otherwise a penalty will be imposed. The female Inspectors also note in their books any nuisances or cases of infectious disease discovered in their district. These are intimated to the male Inspectors, in order to be dealt with by them. There are some of the female Inspectors employed at present in workshops for general inspection. Their hours of work are nine a.m. till five p.m. (one p.m. on Saturdays) with one hour for dinner. The city is divided into six districts for the women Inspectors, and they work immediately under the supervision of the district Inspector; they are, however, responsible to me, not to the Medical Officer of Health. Their wages are £1 a week, and there has been no advance granted during the past fifteen years.

"We have not gone further than this at present in the employment of women as sanitary Inspectors," said Mr. Fyfe in conclusion. "I am afraid, as a rule, their want of technical training will greatly debar women from taking in hand the structural part of a Sanitary Inspector's work; that is to say, with the inspection and supervision of drainage works, and special means of ventilation in workshops, public places, and dwelling-houses. I find also from experience that they are more susceptible to the ordinary wear and tear of such a life than men are, and are not unseldom absent from duty through ailments of one kind and another. For the more domestic part of the Sanitary Inspector's duty, they are, I think, well enough fitted, and by constant visitation exercise a wholesome influence upon those housekeepers who are more or less continually in a state of confusion and dirt. They are also useful for detecting overcrowding."

A SANITARY CISTERN AT LAST.

SOMETHING ABOUT THE INVENTOR AND THE INVENTION.

We have had to wait a good long time for the sanitary cistern, but it has arrived at last. And it has not only arrived, but what is more important still, it has come to stay. Its inventor, it is worthy of note, is neither a plumber nor a sanitary engineer, but a veteran Sanitary Inspector, Mr. Hugh Alexander, a gentleman who enjoys the proud privilege of having served the vestry of Shoreditch in the capacity of chief Sanitary Inspector for the past twenty-five years. Probably few Inspectors in the metropolis have witnessed more striking changes in the course of their official capacity than Mr. Alexander, and certainly in no part of it has



municipal enterprise moved so fast as in Shoreditch. To visit the parish now is to visit a spot where order has been evolved out of chaos. Where the wildest rookeries imaginable once clustered open spaces and model dwellings abound. Where the dull glimmer of uncertain gas once flickered in the streets the electric light evolved from parish refuse now penetrates the gloom; public baths and wash-houses, public libraries, and other signs of improvement and progress all testify that the spirit of enterprise has been abroad in what was once considered one of the most hopeless slum districts of the metropolis.

The post of chief Sanitary Inspector during this period of transition has, it may well be imagined, been far from a sinecure, nor have Mr. Alexander's experiences (which, by the way, we intend to invite him sooner or later to relate to our readers through these columns) been without their periods of anxiety. But he has come out of the ordeal with flying colours, and to-day there is probably no official in the parish who enjoys greater popularity. Mr. Alexander was for many years chairman of the Sanitary Inspectors' Association, in which position he enjoyed the friendship of Dr. Benjamin Ward Richardson, and the progress made by that body owes much to his sound judgment and broad-minded views. So much for the inventor. Now for the invention.

We presume that no one will contend for a moment that the cistern in common use is absolutely perfect. It is quite certain that no such contention will emanate from a Sanitary Inspector, or, indeed, from any person who has had to do with the zinc boxes—for they are nothing else—which builders find a pleasure in fixing up in the most inaccessible parts of our modern jerry-built villas. Who has not at some time or other been brought face to face with one of these abominations, mud an inch deep at the bottom, and a coating of black scum that could be felt on the top? And the average householder goes on drinking his water in spite of it, lulled into a false security by the fact that an analysis of the company's water has been made by Professor So-and-So, and pronounced absolutely germ free and pure. To quote Mr. Alexander:—"However pure water may be as supplied by public mains, it is always more or less polluted in cisterns before it reaches the consumer's lips." And herein lies the *raison d'être* of his invention, which he contends—and in which contention he has the support of the Shoreditch Vestry, who have by a unanimous vote adopted it, the Vestry's architect, and last, and we hope not least, The Sanitary Record—cannot fail, if properly introduced to public notice, to relegate the old-style cisterns into the limbo of sanitary antiques.

We have recently had the pleasure of examining one of these cisterns of 300 gallons capacity, and our views are quite in accordance with those of Mr. Rowland Plumbe, Architect to the Shoreditch Vestry, who describes it as self-cleansing, and adds that, "altogether a perfectly safe and sanitary storage of water is obtained, and that it is a very valuable addition to the many sanitary appliances which of late years have been introduced into house building." The cistern, which formed the object of a demonstration for our special benefit, is, we gleaned, constructed of galvanised iron, and the water is protected from pollution by the cistern being enclosed, only sufficient air being admitted—into a small air-box which is attached to the top—by way of vent, to allow of a free withdrawal of water, and, on withdrawal ceasing, the outer air is again shut off by the action of a very ingenious automatic air valve, by which arrangement also all pressure from the main is precluded. This absence of pressure is a considerable advantage, as the cisterns may be made of any size, and of any shape, without apprehension as to danger that would otherwise arise from the heavy pressure prevailing in some districts. By the same arrangement a warning is automatically given to the householder when the main is shut down, or when the service is in any way suspended. The bottom is sloped from all sides to the outflow, so that no deposit can accumulate. The mechanical construction throughout is of a simple character, as will be gleaned from the appended illustration; and although the cost of the cistern is necessarily a little more than that of the cistern now in vogue,

the advantages are such as to override this objection—if it can be called an objection—a thousandfold.

In conclusion, we commend Mr. Alexander's invention to the notice of Local Authorities generally, and we may add that we do so simply because we have the fullest confidence in its merits, and not only believe it to be the nearest approach to the ideal cistern which has as yet been evolved, but a cistern which has only to be widely known to be generally adopted.

FOOD AND HEALTH: WHAT PEOPLE SHOULD AVOID.

UNDER the auspices of the Glasgow Dairymen's Association, Dr. Robert Bell, Glasgow, delivered a lecture in the Religious Institution Rooms, Glasgow, on the subject of "Food and its Relation to Health." There was a good attendance, presided over by Councillor Gray, who said the health of the community was one of the first questions. In Glasgow they had managed, by observing this fact, to reduce the death-rate considerably. He might mention that the death-rate of Glasgow during 1897 was 22 per 1000, in Manchester it was 23, and in Liverpool 24. Milk had a very important relation to the health of a community.

Dr. Bell alluded to the digestion of foods, and said the more simple the diet the greater were the prospects of health to the individual. It should be borne in mind that people always ate more than was necessary to maintain the general health of the body. This violation tended to indigestion. Over-indulgence in eating was equally as injurious as over-indulgence in alcohol, although the results of that might not be so apparent. Vegetables should be taken fresh, if possible, for he maintained that as a nutritive agency beef tea was of no value whatever. Broth was another food which possessed few nutritious qualities. These gave rise to flatulency, and he had often people coming to him under the impression that they had heart disease when their trouble was caused by their stomachs distending and pressing against the heart.

He next touched on the question of cooking food, and after dwelling on its importance, said it was pitiful to see so many young women wasting their time in cycling—which had a most pernicious effect on their health—instead of attending to their domestic duties. To maintain health it was absolutely necessary that a variety of food should enter into the dietary of every individual. Milk contained all the nourishing elements sufficient for the health of the body, and he mentioned as a proof of this that the Arabs, who were the longest-lived people in the world, subsisted almost entirely on milk. In the treatment of Bright's disease and fevers generally there was no more valuable agent at the command of the physician than a good supply of milk.

A number of questions were answered, and the usual votes of thanks terminated the proceedings.

HUNTINGDON.—A very even death-rate has prevailed in this borough for the past seven years. The average for the period is 63·5. The deaths occurring in 1897 numbered 64, or a rate of 14·6 per 1000 inhabitants.

Institute of Sanitary Engineers

(*Continued from page* 73.)

Those were the difficulties our Government had to contend against during the Indian plague. Some actually secreting the bodies of those who died of this terrible plague amongst the living, rather than the Authorities should know the disorder was in the house. And yet the nation of people under consideration willingly subjected themselves, and gave every facility to the priest for inspecting their houses, their clothing, and their bodies.

Since the passing of these Acts in England great stimulus has been given to all sanitary reform. Where are the appalling epidemics of diseases as experienced in former years? Take the Maidstone one as the most serious experience for some time; yet, by careful isolation and prompt action, the Authorities prevented what might have been even much more serious.

So far, we have only dealt with the Jewish laws regarding the body. Yet they possessed a law for houses to be disinfected, and evidently in a most systematic manner. What the leprosy in house and in the clothing was I am not quite prepared to say. Some say it appeared first in the house, then in the clothing, and lastly in the person. Certainly if our modern scientific experts tell us that the clothing taken from a room where an infectious disease may have broken out, or the bed upon which the patient may have lain should either be put into a hot-air disinfecting chamber to kill the germ, or destroyed by fire, or a house should be thoroughly cleansed and disinfected, and yet nothing is visible in appearance.

It will not then be difficult to believe it possible that leprosy would cling or attach itself to a house which evidently was plastered, and probably size or some animal or vegetable matter mixed with it. Nor yet would it be difficult to understand it attacking the garments which were worn. The care and means taken to cleanse and purify infected clothing and houses was surprising. Clothing was generally burnt—a most effectual way of stamping out a plague.

In the houses the floors and walls were scraped, washed, and re-plastered; all that was scraped off was carefully carried outside the camp or city. If, however, it again appeared, the walls of the house were pulled down and the *débris* carried away.

There was no evidence to show whether this leprosy in the walls appeared similar to our fungus, which, we know from experience, when once it gets a hold, spreads rapidly, and as it spreads, frets or eats away the part attacked. A few years ago, in making a sanitary alteration in a mansion-house in Scotland, I found that the fungus had spread from the basement up behind the lath and plaster, eating away the wood lintel and woodwork in general, in some parts actually reaching a portion of the lower roof. I thought a word about this might raise a profitable discussion. Experts tell us that air is required, which I quite believe, yet you must have noticed it growing outside, where a free circulation of air was obtained. I have noticed old floors taken up which must have been down at

least thirty or forty years, and no trace of the growth. Yet a new floor, under the same and sometimes more favourable conditions, entirely eaten away within twelve months. I sometimes think the wood itself has something to do with its generation.

One other matter which must strike us, was the means employed to cleanse the camp or city of any nuisances. All animal or vegetable refuse was ordered to be either burnt by fire or carried outside the camp. When we consider the number of people which, according to history, is 600,000 fighting men above twenty years of age, along with the women and those below twenty, would give us an aggregate total of at least two million people.

The disposal of nuisance and excremental matter to such a number of people would, in the present day, be a most serious and important item. This I may say appears to me one item in which we have made most rapid strides, in the disposal of refuse and sewage matter, owing, no doubt, in a great measure to the fact that the nation has made it worth the while of men of capital, men of energy, and men of brain, to spend their lives in searching out, and inventing methods, and manufacturing machiney, capable of being utilised for such purposes.

The Jewish people had a very primitive method. "Thou shalt have a place also without the camp, whether thou shalt go forth abroad." "And thou shalt have a paddle upon thy weapon; and it shall be when thou wilt ease thyself abroad thou shalt dig therewith and shall turn back and cover that which cometh from thee."

This, I think, is quite suggestive enough, without further explanation, but certainly much more preferable to an old law which existed in London, as follows:—

"No man shall cast any urine or ordure-boles into the street before the hour of nine at night. And also he shall not cast it down, but bring it down and lay it in the channel, under the pain of three shillings and fourpence.

"And if he do cast it upon any person's head, the party to have a lawful recompense, if he be injured thereby."

Pedestrians must certainly have had a lively time dodging the contents of these utensils.

I have now to touch upon the food laws. These people have always been looked upon as very shrewd, and there are one or two points which give us a sidelight which identifies them with their present offspring. They were prohibited from eating that which had died in the field—it was to be destroyed—only they were allowed to sell it to strangers outside the camp. There are still a number of people who believe in this Act. Many a farmer knows the law prohibits him from sending the same to market, nor yet would he eat it himself, yet would not hesitate to sell it to some unscrupulous party to re-sell. Where, or how, he asks no question, for conscience' sake.

As regards swine flesh little need be said, while we may all like a little pork, or rasher of bacon for breakfast, yet, nevertheless, to see the beast feed, and especially in Eastern climates, it cannot be termed clean. Or did they know anything about the diseases which the system sometimes suffers through eating the flesh? Many of the birds of the vulture tribe we can at once pronounce as unfit for human food. There is one animal, however, which most English people delight in, yet was counted by them unclean, that is the hare. Why it should be so no one gives a reason; but it is a fact that hares, although clean living animals, are most subject and predisposed to tape-worm.

As to social hygiene, as far as cleanliness of body, of garments, and houses was concerned, many might yet draw a valuable lesson. If they came in contact, accidentally or otherwise, with any form of pollution or defilement, it meant a thorough cleansing. Strict law also existed to keep unpolluted any wells of water or streams from which they received their supplies.

Why was it that cleanliness was so essential? The reason which appeals to us is the same feeling which prompted the great artists in building the temples to the god and goddesses in Greek mythology, in which the sculpture work was perfect; let it be ever so high and out of the sight of men, prompted the Israelites to cleanliness. The former believed that their deities could see and look into every little detail; while the latter believed that God walked abroad in their camp, and that no uncleanliness should be seen by Him.

Just a word about our own Public Health Laws. There is, perhaps, no country in the world that can boast of such complete sanitary laws, and such equity shown in the discharge of the same.

In this our Government have done well. What we want now is really to educate the masses of the people up to this hopeful sanitary Utopia. There are three great mediums which must work to accomplish this. The School, the Pulpit or platform, and the Press.

I consider it one of the duties of our Government to cause instruction on the laws of hygiene, &c., to be given to the children in elementary Government Schools. That the clergy should see that there is nothing more conducive to raise the social and moral tone of a community than pure air, pure water, and thorough cleanliness, I am pleased to state that the Church is realising this fact, and good work has and is being done by the existing Church Society, and thirdly, by the mighty influence of the Press, they may be brought to some practical issue. It is no use lecturing to a man that he requires so much air space for the proper maintenance of a healthy body, while the circumstances in which he is placed compel him, his wife and family, to huddle together in one small room. Neither could we tell that man of the necessity of keeping his own body clean, if we don't provide ample provision for allowing him to do so.

Thanks to the sanitary legislation of these last ten or twenty years, which embraces the causes of deterioration and disease of the human system; that is to say, the material causes, such as impure air, impure water, insufficient and unwholesome food, dampness in soil and houses, deficiency of warmth, &c. The removal of the above causes is the principal aim of all practical hygiene as enforced by our legislative enactments.

There is yet another means I should like to mention, which has been instrumental in strengthening the hands of the Government in these matters. That is institutes and associations, such as the Sanitary Institute, the Institute of Sanitary Engineers, the City and Guilds, the Worshipful Company of Plumbers, and the Church Institute,

through meetings held, publications printed, and technical education given, the way continues to be made easier for our Government to extend its legislative powers.

An interesting discussion followed, in which Messrs. DOVE, STOVOLD, WELLS, MAYNER, RAYNER, LOWE, and PALMER took part. In conclusion a hearty vote of thanks was voted to Mr. McAdam for his very able paper.

General News.

HOME.

NOTICE.—On and after 31st March next the Annual Subscription to this Journal will be raised to 12s. 6d. to all NEW Subcribers. NO ADVANCE will be made to our friends whose names are entered on our Subcription list prior to that date, so long as they continue to Subscribe.

CUMNOCK.—A site has been approved for the erection of a district hospital.

WALSALL.—The Town Council propose to erect an isolation hospital, principally for small-pox cases.

GODMANCHESTER. — The Medical Officer of Health reports that the death-rate for the past year is 16·2 per 1000.

RHYL.—A town's meeting has been held at which a resolution was adopted calling upon the Council to take steps to put into force the Housing of the Working Classes Act.

ANCOATS. — In connection with the Ancoats Healthy Homes Society on Thursday week, Dr. Worswick gave an instructive lecture on the "Human Body," illustrated with limelight lantern views. This society is doing a splendid work in encouraging the study of hygiene by the people.

HENLEY.—By direction of the Rural District Council four samples of water have recently been analysed; two of these were taken from Charney and two from Farringdon. The report of the analyst condemned the two latter as unfit for drinking, and also deemed those from Charney as unsatisfactory. The report has caused considerable anxiety in the district.

MERTHYR.—At the last meeting of the Urban District Council it was reported the Council in committee had adhered to the opinion that the Sanitary Inspector had not exceeded his duty in regard to the reporting of infectious diseases. He had only inspected the surroundings of the reported cases, and did not, as had been asserted by medical men of the district, attempt to diagnose any of the cases referred to. The report was adopted.

SHIELDHALL. — Considerable extensions have now been completed to the Govan Combination Hospital, and the new portion was formally opened last week by Provost Kirkwood. The cost of the additions is estimated at £12,550, of which £11,500 were for buildings and £850 for furnishing. This brings the total expenditure on the hospital up to £37,800, or an average of £378 per bed. One improvement made is the discharge of the sewage from the hospital in a sewer running direct to the outfall instead of an "open burn" along the east side of the original site.

SOUTHILL.—There is a bad outbreak of measles in this parish. The schools have continued closed, and many adults are victims of the epidemic.

PRESTWICH.—The complaints recently made as to the impurity of the water supply are stated by the Medical Officer to be without foundation.

COVENTRY.—The City Council, advised by Mr. Hawkesley, has decided to oppose the Bill being promoted by the North Warwickshire Water Company to supply the parishes of Foleshill, Exhall, Sowe, Wyken, Stoke, Binley, Keresley, &c, with water, on the ground that it involved danger to the Corporation's water undertaking.

NORWICH.—At the last meeting of the Corporation, Mr. C. E. Muriel moved the adoption of the recommendation of the Sanitary Committee as under:—"That the isolation hospital be altered and enlarged, and wards for scarlet fever, typhoid fever, diphtheria, and discharging patients, and a porter's lodge with residence over for the Medical Officer be added thereto, and additions be made to the laundry, kitchen, and heating apparatus, at a cost estimated by the City Engineer at £7000." After some discussion the debate was adjourned.

MIDSOMER NORTON.—The report of the Medical Officer of Health (Dr. Whicher) for the year 1897 showed the health of the district to be excellent, with a continued low rate of mortality. There was also a marked diminution in the number of notified cases of zymotic diseases—13, as against 33 in 1896. The estimated population in June last was 5550. Births registered: Boys, 89; girls, 96; total, 185; or a birth-rate of 33·33 per 1000. Sixty-five deaths were registered, being one more than last year, and at the rate of 11·71 per 1000. The infant mortality was 64·81 per 1000.

NORWICH.—Two years ago the Corporation arranged for slop-water closets to be fixed in a portion of its district. Complete satisfaction is expressed with them. In a report recently presented the city engineer states that notwithstanding a stringent watch no waste of water has been observed in consequence of its construction, and at no time has it been a nuisance in any way. In every respect the slop-water closet is a very great advance on the pan closet it replaced; it is as much superior to the bin closet; and in many respects for outdoor closets is preferable to water-closets. The slop-water closet requires absolutely no supply of water whatever beyond the ordinary waste of the household; it is not subject to being put out of action by frost; the concentrated flushes tend to keep the house drains in good working condition as compared with middens, bins, or other such abominations; offensive matter is not retained in the neighbourhood of houses for more than an hour or two, instead of for days, weeks, or months; the cost of removal is nothing, it being done automatically by the flow of waste water; the addition to the flow of sewage is very trifling; the difference in the cost of pumping, treatment, &c., is inappreciable; and the nuisance arising from the old system of collection is entirely obviated. The water supply of the city is economised as compared with that required for water-closets, in that, as for slop-water closets, there is absolutely no water required beyond the ordinary waste of the house.

RAMSEY.—Borings are being made in order to discover a source for a pure water supply.

BROMYARD.—Consent to a loan of £550 for purchase of a steam roller has been received by the Rural District Council.

BERWICK.—The Works Committee has under consideration the advisability of erecting lavatories for ladies in the town.

WHITECHAPEL.—Tenders are to be invited for the supply of twelve new water vans for use in the district at the estimated cost of £45 each.

TRURO.—Mr. J. Retallack, Sanitary Inspector, reports a marked improvement in the sanitary condition of the district. In 1897 he served 424 notices to abate nuisances and provide water supplies.

BIRMINGHAM.—A Local Government Board inquiry has been held into the application of the City Council for sanction to borrow £10,000 for lunatic asylum purposes, and also to borrow £12,510 for the erection of a refuse destructor at the Montgomery-street Wharf.

LONGTON.—A special meeting of the Sanitary Committee of the Town Council was held recently to consider the present state of things in regard to the diphtheria epidemic. The committee, as the result of their deliberations, decided that all the schools should be again closed for a period of a month.

BIRMINGHAM. — The Association of Birmingham Students of the Institution of Civil Engineers held its fourth ordinary meeting of the session on the 20th inst., at the Midland Institute. Mr. W. Bayley Marshall presided over a good attendance. Mr. A. Burton read a paper descriptive of the Hanley sewage works. The paper was subsequently discussed at length by the students.

MERIDEN. — The Rural District Council has appointed a committee to confer with Mr. Willmott, County Surveyor for Warwickshire, as to the best means of obtaining a pure supply of water for the Marston Green district, Dr. Bostock Hill and Messrs. Southall, Birmingham, having reported that six samples of water submitted to them for analysis were little less than clarified, and contained partially oxidised sewage.

GLASGOW.—Mr. Gale, the Engineer, reports that the quantity of water sent into the city and district during 1897 averaged as follows:—From the Loch Katrine works, 46,196,731 gallons per day; from the Gorbals works, 4,782,797 gallons per day, total, 50,979,528 gallons. Compared with the previous year, the average daily total shows an increase of 1,822,485 gallons. At the River Supply works the quantity of water pumped for supply to manufacturers averaged 2,572,841 gallons per day, an increase over the previous year of 27,455 gallons daily. Regarding the new works, Mr. Gale states that the driving of the tunnel through Loch Katrine Hill continues to progress at the rate, on an average, of forty lineal yards per month at each face. The length driven during the past year has been 976 lineal yards, which leaves 643 yards still to do, and at the rate of forty yards at each face the whole will be completed by the end of August, after which there will remain the concreting inside, and the basins at the inlet from the Loch, to complete the contract. The other new works are also progressing.

NORTHWICH. — A Local Government Board inquiry has been held into an application of the Rural District Council for sanction to borrow £520 for works of water supply for the townships of Cuddington, Hartford, and Weaverham.

TOTTENHAM.—A Local Government Board inquiry has been held at Coombe's Croft into the application of the District Council for sanction to borrow £1500 for extension and enlargement of water mains in Philip-lane and West Green-road. There was no opposition.

MAIDSTONE. — The Local Government Board inquiry on the recent typhoid epidemic will be opened on Monday next, the 31st inst., at the Town Hall. At the last meeting of the Town Council a resolution was carried asking the Local Government Board to postpone the inquiry until Dr. Thomson's report had been presented, but the Board intimated to the Corporation that they did not consider sufficient grounds had been shown for postponing the investigation.

NEWTON ABBOT. — For the fourth quarter of 1897, Dr. Harvey reports a death-rate of 10·4 per 1000, against 14·6 in the corresponding period of 1896. Commenting on these figures, Dr. Harvey says, that although the death-rate was a highly satisfactory figure the age distribution of the mortality was very bad, as no less than ten out of twenty-five deaths were in infants under one year, and two between one and five years; eight were, however, in persons over sixty-five years.

MANCHESTER.—The Corporation Committee has reported on the suggested purchase of the Royal Infirmary and site. It is recommended that the Corporation pay, and the Trustees of the Infirmary accept, the sum of £286,000 for the Infirmary land, and the various rights and arrangements which were the subject of consultation. This purchase-money is equal to a price of £25 per square yard if the esplanade be excluded from the computation. If the esplanade be included in the calculation, the price for the land to be absolutely vested in the Corporation for ever is equal to £18 10s. per square yard.

ABROAD.

GERMANY.—According to the Berlin correspondent of the *Standard* the *Reichszanzeiger* publishes a long and rather unfavourable report on the foot-and-mouth disease in Germany. It has never quite died out since July, 1887, and has since then attacked all parts of the empire. Investigations have shown that the micro-organisms which have been regarded by a good many *savants* as the cause of the disease, especially Siegel's bacillus and Kurth's streptococcus, have nothing to do with it, and that the true origin has not yet been found, probably because the ordinary bacteriological method is unequal to the task.

CANTERBURY, NEW ZEALAND.—Following the course adopted last year the side channels in the streets of the city, in which there are no sewers, and in which houses have consequently to be drained into the street channels, are again being regularly cleansed with disinfecting fluid, and will be during the summer months. One or two amusing incidents are recorded in this connection. Some persons have mistaken the fluid, which turns white in water, for soapsuds, and have laid complaints accordingly. The fluid is carried by the sweepers

in large flasks, and it is said that an individual who noticed one of the men putting one of these receptacles into his coat pocket, reported him for surreptitious drinking in working hours.

Personal.

MR. A. PURKISS has been appointed Inspector of Nuisances for the borough of Andover.

MR. R. LORD has been appointed Inspector of Nuisances for the Borough of Loughborough.

MR. W. A. PEAKE has been appointed Inspector of Nuisances for the rural district of Gnosall.

MR. J. W. WEBSTER has been appointed Inspector of Nuisances for the urban district of Cowes.

MR. G. HOPE has been appointed Medical Officer for the seventh district of Brentford Union.

MR. J. WORRALL has been appointed Inspector of Nuisances for the urban district of Long Eaton.

MR. M. M. HARLEY has been appointed Medical Officer of Health for the urban district of Newport Pagnell.

MR. H. P. TOPSFIELD has been appointed Vaccination Officer for the Rayleigh district of Rochford.

MR. A. E. NORMINGTON has been appointed Medical Officer of the Stoke-upon-Trent Workhouse.

MR. E. T. WHITAKER has been appointed Medical Officer of Health for the rural district of Blymhill.

MR. T. F. WOODHEAD has been appointed Medical Officer of the Meltham district of Huddersfield.

DR. DARBY has been appointed Medical Officer of Health to the Lye and Wollescote Urban District Council.

DR. ROBERT BROWNE has been elected Medical Officer at Rathmines in succession to the late Dr. Montgomery Ward.

DR. JOHN BRADFORD has been appointed Medical Officer for the Parish of Carluke, in room of the late Dr. Robert Stewart.

MR. F. G. SKINNER, of Wakefield, has been appointed Surveyor and Inspector of Nuisances for the rural district of Norman Cross.

DR. R. B. BARR has been appointed Certifying Surgeon for the civil parish of Carluke under the Factory and Workshops Act.

AT the last meeting of the Police Commission of Forfar, Mr. T. M. Inglis, V.S., was appointed Veterinary Surgeon under the Public Health Act of 1897.

MR. E. A. SANDFORD FAWCETT, C.E., F.G.S., of 1, Victoria-street, S.W., has been appointed a temporary Engineering Inspector at the Local Government Board, and Messrs. John Taylor, Sons, and Santo Crimp, C.E., of 27, Great George-street, S.W., have taken over his practice.

Sewerage Schemes.

[TO MUNICIPAL ENGINEERS AND SURVEYORS.—The Editor will be pleased to receive items for publication relating to sewerage schemes projected or inaugurated, together with explanatory diagrams or photographs. The former should be drawn and lettered in black ink.]

THE sewage works for Pleasley (Notts) are now completed.

THE County Council of Dumbarton has sanctioned the borrowing of £4000 for the Duntocher drainage scheme.

A DEPUTATION from Manchester Corporation visited Glasgow recently to inspect the Dalmarnock sewerage works.

THE Plaistow Highways Committee is considering a plan for the surface-water drainage works at Plaistow-lane.

AN application to the Local Government Board to borrow £12,000 for a sewage disposal scheme for Armagh has been made by the Armagh Town Commissioners.

A SCHEME for dealing with the Doveridge sewage by precipitation and filtration through artificial filters will be discussed at the next meeting of the Sudbury Rural District Council.

AT a meeting of the St. Austell District Council a letter was read from the Local Government Board suggesting that the Council should employ a competent sanitary engineer to prepare a scheme for the disposal of the sewage of Tywardseath.

A LOCAL Government Board inquiry has been held at Evesham into the application of the Rural District Council to borrow £2000 for sewerage works at Badsey. The Parish Council of the latter place opposed chiefly on the question of cost.

AT a special meeting of the Rhymney Urban District Council an agreement for the acquisition of a site of four acres for the sewage disposal works at the Mardy at a cost of £1750, subject to the approval of the Local Government Board, was sealed.

ANOTHER step towards the realisation of the Glasgow sewage scheme will shortly be taken, as in the ensuing session of Parliament the Corporation will apply for powers which, if granted, will ensure that the whole of the sewage of the city and burghs on the south side of the river will be conveyed to the purification works at Braehead by a double system of sewers. The quantity of sewage which will then be dealt with will, it is estimated, be about twenty-four million gallons daily.

THE Hungerford Rural District Council at its last meeting unanimously passed the scheme of drainage and sewage disposal submitted by E. W. Ives, C.E., of Derby, and it was resolved to at once apply to the Local Government Board for sanction to borrow £4000 to carry out the scheme.

A LOCAL Government Board inquiry was held at Kibworth on the 20th inst. in reference to an application of the Market Harborough District Council for sanction to borrow £3550 for the purposes of sewerage and sewage disposal for the parishes of Kibworth Beauchamp and Kibworth Harcourt.

ON Thursday afternoon, the 20th inst., Colonel C. H. Luard, R.E., one of the Local Government Board Inspectors, attended at the Guildhall, Poole, for the purpose of inquiring into an application made by the Poole Town Council for sanction to borrow the sum of £622 for carrying out works of street improvements and sewerage.

AT a recent meeting of the Isle of Wight Rural District Council the Council considered the General Purpose Committee's report as to the sewerage scheme for Freshwater. The committee recommended that the principle of the scheme prepared by Mr. George Chatterton be adopted, and this was done. It was stated that the scheme, which involved a high-level and two low-level sewers, the latter to be pumped up into the higher level sewer, would probably cost £20,000, only £1000 of which would be spent in sewering Totland.

AT a special meeting of the Morecambe District Council on Friday, the 20th inst., the twelve competitive schemes for the sewerage of the district were again considered, and eventually the scheme submitted by "Forward" was adopted. The scheme will serve for a population of 60,000, and the estimated cost of the works is £39,227 10s. 9d. (exclusive of way leaves, engineering, or land). The successful competitor is Mr. H. B. Nichol, C.E., 60, Corporation-street, Birmingham. The cost of the schemes submitted varied from £19,000 to £66,000 (not including working expenses). The scheme will now be submitted to the Local Government Board for approval.

THE Llanishen sewerage scheme, which has extended over twelve months, is now complete, and consists of about six miles of stoneware pipe sewers, varying in size from 9in. to 18in. internal diameter, having an outfall into the Ystradyfodwg and Pontypridd main sewer at a point near Fairoak Farm. The sewers are constructed on the duplicate or separate system, that is, the subsoil and surface water is excluded from the sewers, and the pipes are of sufficient size, and laid to a gradient to carry off a known quantity of sewage, with slight variation, all the year round, and calculated to be of sufficient size to meet the requirements of the district for forty years to come. The road gratings of the man-holes and lamp-holes are made air-tight, and cast iron ventilators are being erected, fitted with an apparatus for the consumption or burning of the sewer gas before being discharged into the air. Automatic flushing tanks, each containing not less than 1000 gallons at each discharge, are provided at suitable places. The sewers are laid in straight lines from man-hole to man-hole or man-hole to lamp-hole, which are constructed at each change of gradient or direction, thus enabling any obstacle or stoppage to be detected and removed without opening out any part of the sewers. The pipes used were those manufactured by Messrs. Noel, of Llantrisant, with the exception of some cast iron and Sykes' patent jointed pipes where large springs were met with. Wm. Evans was Clerk of Works; Messrs. Batchelor and Snowdon, engineers and contractors, Cardiff, were the contractors; and Mr. Wm. Fraser, A.M.I.C.E., &c., the Surveyor to the Llandaff and Dinas Powis Rural District Council, was the engineer.

Lighting.

A COMPANY is being promoted at Worle for the purpose of erecting gasworks.

PLANS for new works at Friarton have been approved by the Gasworks Committee of Perth.

IN view of the success of the incandescent lighting in the main thoroughfares of Greenock, it has been decided to apply the system in Shaw-street and Dalrymple-street, between Rue-end-street and Nicolson-street.

IN consequence of the numerous complaints as to the quality of the gas supplied to Norwich, the Town Council has given its committee power to incur any necessary expense to have the gas more frequently tested.

A CORRESPONDENT of the *City Press* states that in consequence of the high price charged for electric current in the City of London (8d. per Board of Trade unit), some of the consumers have reverted to the use of gas.

AN extension of the electric plant of the Southport Corporation has just been completed. The present capacity of the works is more than five times as great as it was when the installation was laid down just over three years ago. Even with this addition, it is expected that the capacity of the installation will be overtaken next winter.

NOTWITHSTANDING the fact that few rural towns in Scotland are ahead of Alloa in the matter of gas lighting, the local Commissioners have favourably considered a scheme for the introduction of electric light. They anticipate that the installation will cost a trifle under £3000, and that the total charges will not be more than £435 per annum, which is only £134 more than they are at present paying for gas light.

THE Tottenham and Edmonton Gas Light and Coke Company, at a meeting on February 5th, will consider their Bill now before Parliament, entitled "A Bill to make further provisions as to the capital of the Tottenham and Edmonton Gas Light and Coke Company, and to empower them to supply electricity, and for other purposes," which will be submitted for the approval of the proprietors.

THE report of the Electric Lighting Committee of the Chester Town Council shows that after providing for interest on capital, and the amount required to be laid by for the sinking fund, a profit remained of £561. Of this sum £421 was returned to consumers in the shape of an extra discount, and £141 was carried forward to next account. The Town Council have given notice to take over the electric lighting works in March next.

A REPORT has been issued to the members of Glasgow Town Council on the question of the electric lighting of the Springburn tramway route, upon which the experiment in electric tramway traction is to take place. The Electrical Department report that the necessary mains required to be laid down will cost £12,566, which includes provision for private lighting purposes. The cost of electric energy for the whole of the proposed 104 lamps is estimated at £1872.

AT the last meeting of the Sub-Gas Committee (Meters and Mains) of the Leeds Corporation it was decided to reduce to seven the list of applicants for the post of Superintendent of Gas Meters and Mains, the salary for which is £250 a year. The seven from whom the final choice will be made are :—Messrs. James Halton, Halifax; Arthur Grafton, Tunbridge Wells; Ernest Johnson, Nottingham; R. H. Garlick, Salford; George Ball, Birmingham; O. J. Preston, Brentford; and Walter Hole, Rochester.

THE movement to introduce electric lighting and traction in Kirkcaldy is making satisfactory progress. Professor Alex. B. W. Kennedy, LL.D., F.R.S., M. Inst. C.E., of London, has met the Tramways and Town Council Committees with a view to reporting on the proposed combined scheme of electric lighting and traction. Professor Kennedy recommended the combined scheme, which had no engineering difficulties, and was being carried out in other towns, and he approved of the overhead electric system of traction.

"IN consequence," says the *Gas World*, "of the saving on incandescent gas lighting in Berlin public lighting, all the public lamps are to be adapted to this system. Out of £5000 granted for the extension of incandescent lighting in 1897, £4500 has been spent on about 4300 lamps. A further sum of £3125 is to be spent on 3479 lamps, without delay. Of the 22,006 public lamps, 11,483 are already worked on the Welsbach system, and the saving between April 1st, 1896, and October 1st, 1897, is stated to have been 154,000,000 cubic feet. When the transformation is complete, it is computed that the consumption will be 350,000,000 cubic feet per annum instead of 595,000,000."

MR. W. GIBBS presided at a special meeting of the Redditch Urban District Council, held on Thursday evening, to receive from Mr. McMullen, electrical engineer, the plans and specifications in connection with the electric lighting scheme for the town. From the canvass of the town, it was evident that 2000 16 c.p. lamps, or their equivalent, would be connected to the mains. Such a number of lamps would consume about 60,000 units, bringing in an income of £1500 at 6d. per unit. The cost of running the station for that purpose would be £650. The total yearly expense, including this sum, would be £1290, showing a profit of £210. Street lighting was a matter for experiment on the spot after they had got the mains in the streets. Mr. McMullen was instructed to advertise for tenders for the work.

Law Cases.

DEFECTIVE DRAINS.

MR. HOWARD MORRIS, C.C., solicitor, of Walbrook, appeared to an adjourned summons taken out at the instance of the Islington Vestry for not complying with an order made by Mr. Bros directing him to put the drainage of a house he owns in Wyatt-road, Highbury, into a condition satisfactory to the Vestry.

Mr. BRAMALL appeared for the Vestry; Mr. BODKIN, barrister, was for the defendant.

Mr. BODKIN raised the preliminary point that the order was bad. Sub-Section 5 of Section 5 of the Public Health Act provided that, if the person on whom the order was made so required, the works to be done should be specified in the order. He would show that Mr. Cobban, who appeared for the defendant when the order was made, asked that the works to be done should be specified, but a month afterwards, when the order was served, it was found that no works had been specified. By that time the right to appeal had been lost.

Mr. BRAMALL said that he should be able to show that no requisition, as contemplated by the Act, was made.

James Henry Stanlake, clerk to the defendant, said that he was present in court when the verbal order was made. Mr. Cobban asked what works were to be done. He wanted them specified. The magistrate then said he would make the order for the work to be done to the satisfaction of the Vestry.

Mr. BROS: That is the order I meant to make. I meant it to apply to the whole drain.

Mr. BODKIN: We contend, Sir, that you did not say enough. Having been requested to specify the work to be done, you should have done so. All the notice said was "Drain defective," and that defect was remedied before the order was made.

Mr. BRAMALL said that the Vestry had opened the ground, and it had been found that the drain would not stand the water test.

Mr. BODKIN said that was because the workmen broke the pipe in the examination.

Mr. BROS said that he intended the order to apply to the whole drain.

Mr. BODKIN protested that his client could not be expected to expose the whole of the drain to look for defects. The Act of Parliament gave the

Vestry ample power to find out what defects existed, and then they could specify them and compel the owner to do the work. But if they opened up the drain and found no defect then the Vestry had to bear the expense. Mr. Morris was contesting the matter upon public grounds. The Vestry distributed their notices broadcast, then came into Court, where they obtained verbal orders, which they afterwards drew up in their own way. Really their proceedings were most unfair.

Mr. BRAMALL said the strictures which had been passed on the Vestry proceedings were without a tittle of foundation.

Mr. BROS said that if the defendant was not prepared to have the order quashed by another tribunal he must obey it.

Ultimately, after a long discussion, Mr. BROS said that it seemed to him that the only question for him to consider was the amount of penalty to be imposed for disobedience.

The case was further adjourned in order that the magistrate might read the correspondence.

Notes and Queries.

[Subscribers have the privilege of obtaining advice in this column on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed to THE EDITOR, "Notes and Queries," THE SANITARY RECORD, 5, Fetter-lane, London, E.C 1

NOTE.—If an answer be required immediately, a stamped addressed envelope must be enclosed, when we will endeavour to furnish a copy of the answer by post, as owing to the large number of queries received we cannot guarantee the insertion of a reply in the succeeding issue.

948.—ACCUMULATION OF MANURE: PROCEDURE TO OBTAIN REMOVAL. — "Terry" writes: — "In this district a cab proprietor deposits manure from a stable, where four or five horses are kept, in a yard which is complained of by the tenant of an adjacent cottage as being a serious nuisance. The manure heap is adjacent to the wall which separates the yard from the street. (1) Will you please advise as to how often the manure should be cleared away? (2) Does the sanitary law define the distance at which such a manure heap must be constructed from a dwelling-house, if so, please state distance and section of the Act. I enclose plan of locality."

Answer.—(1) Presuming that this is an urban district the following sections will apply to the case, viz.:—(*a*) Sec. 49 of the Public Health Act, 1875, where the Inspector of Nuisances may on its appearing to him that any accumulation of manure, dung, soil, or filth, or other offensive or noxious matter, ought to be removed, he shall give notice to the person to whom the same belongs to remove the same, and if not so removed within twenty-four hours, it shall be vested in the Urban Authority and removed and sold by them, &c. (*b*) Sec. 50: Notice may be given by the Urban Authority, by public announcement or otherwise, for the periodical removal of manure or other refuse matter from mews, stables, or other premises, and where any such notice has been given any person to whom the manure, &c., belongs who fails to remove the same, or permits a further accumulation, and does not continue such periodical removal at such intervals as the Urban Authority direct, shall be liable without further notice to a penalty not exceeding 20s. for each day during which such manure is permitted to accumulate. (*c*) Secs. 91 to 96: The accumulation of manure may be a nuisance as defined by Sec. 91, and proceedings may be taken under the sections following. (*d*) Bye-laws with respect to nuisances. If bye-laws on this subject are in force in the district, it will probably be found that a clause exists similar to Clause 12 in the Model Series of Bye-laws which regulates the construction of premises for cattle, horses, swine, &c., and which prescribes the removal of dung weekly or some other period. (2) Neither the Public Health Acts nor Bye-laws prescribe the distance at which manure heaps may be constructed from dwellings. Our correspondent should communicate with the Sanitary Authority or their Inspector, who should be able and willing, we think, to assist him in obtaining the abatement of the nuisance.

949.—MARKETS AND FAIRS CLAUSES ACT, 1847: RECOVERY OF TOLLS. — "Surveyor" writes: — "I have been appointed Collector of Market Tolls to this Urban District Council. It has long been the custom to sublet the tolls, but this year, there being no bids for them, their collection was placed in my hands. Our lease with the lord of the manor contains the words, 'To collect tolls, fees, and charges for any sale or attempted sale in the market square, streets or other places in the lordship.' We lose a considerable amount owing to farmers and others, who bring large quantities of fowls to the town, putting up their conveyances at the inns, and calling in at the fowl dealers from the market square, who buy the fowls and bring them into the market. If we demand the toll from the dealer, he refuses to pay, saying that he has bought, not sold, while, if we apply to the farmer, he refuses on the ground that he did not sell in the streets, but in the public house, the consequence being that we get a lot of fowls on the market square, three-fourths of which have evaded the tolls. The dealer pays for the few he brought to the market, and so claims

ANTISEPTIC

DISINFECTANT.

DEODORANT.

INODOROUS DISINFECTION.

Absolutely Non-Poisonous, Non-Corrosive, Non-Volatile, and does not Stain.

See published Bacteriological Report by Dr. E. KLEIN, St. Bartholomew's Hospital, London.

CHINOSOL SANITARY TABLETS are the most convenient, most effective, and most economic for the immediate production of Disinfecting Fluids. **12 Tablets**, packed in one tin to carry in waistcoat pocket, price **2s.** One Tablet in warm or cold water produces in **less than one minute**:—

3 Quarts of a strong Deodorant and Disinfectant, sufficient to spray one infected room of 1000 cubic feet; or
3 Gallons of a strong Disinfectant for flushing drains, walls, floors, &c.

Literature (Dr. Klein's Report) and Samples free to the Profession.

B. KUHN, 36, ST. MARY-AT-HILL, LONDON.

Telegraphic Address: "CARMINES, LONDON. Telephone: Avenue 5976.

a standing. Will you kindly advise me what course to pursue? Also what is the best step to take when a man selling goods on the market refuses to pay his toll?"

Answer.—The district is that of an Urban District Council. Assuming that the Council have been empowered, as required by Sec. 166 of the Public Health Act, 1875, to purchase the private rights in the market, and to take stallages, rents, and tolls in respect of the use by any person of such market, and that the tolls leviable, as provided by Sec. 167 of the Act, have been approved by the Local Government Board, the Urban Authority are entitled to recover tolls, after the market place is opened for public use, from every person other than a licensed hawker who shall sell or expose for sale in any place within the prescribed limits, except in his own dwelling-place or shop, any articles in respect of which tolls are by the special Act, *i.e.*, the Public Health Act, 1875, authorised to be taken in the market, and any person selling any article in contravention of this section, shall for every such offence be liable to a penalty not exceeding forty shillings (Sec. 13, Markets and Fairs Clauses, Act, 1847). If tolls are leviable on fowls, as we have no doubt such will be the case, the Urban Authority, through their duly appointed collector, may recover the tolls from the vendors of the fowls, if such be sold after the market place is opened, and within the district of the Local Authority, notwithstanding that such may have been sold at inns or places other than the market square. If any person liable to the payment of toll refuse to pay the same on demand from the person appointed to collect the same, the collector may recover the tollage by distress, as in the ordinary case of rent, or he may recover the same by action in a court of summary jurisdiction. The collector should, through the local Superintendent or Inspector of Police, obtain the assistance of a police constable, in probable cases of dispute or refusal to pay tollage, for corroborative evidence in case of summary proceedings being necessary, or where it may be necessary to levy a distraint on any animals or articles brought to the market.

950.—Bye-laws as to New Streets: Surface Water Sewers and Drains.—"J. W." writes:—"The District Council of R—— have put down sewage works on the precipitation and filtration principle of the International Company's process, the precipitant used being Ferozone. Until recently storm-water from streets, houses, and backyards, passed into the sewers. Owing to the cost of Ferozone, the Council have passed a resolution that unless the plans for new houses show separate drains for conveying away surface water from roofs and backyards, such plans will not be approved. The Council have not yet put in storm-water sewers to receive surface water, and there is no bye-law in regard to storm-water drains. (1) Can the Council simply by a resolution refuse to pass plans of a new street unless both storm-water and sewage sewers are shown to be provided by the persons making new streets? (2) Can the Council refuse to pass plans which are in accordance with their bye-laws, but which do not show duplicate drains? (3) The Council not having provided storm-water sewers in their streets, can they require owners to put in duplicate drains in backyards, and begin a separate system of drains until they provide storm-water sewers themselves to receive the said storm-water?"

Answer.—(1) Unless the Bye-laws of the Local Authority contain provisions as to the sewering of the streets, we are of opinion that they will be unable to disapprove plans otherwise in conformity with the bye-laws, because sewers are not shown. See our answer to Query No. 905 in our issue of December 24th last. (2) We do not think so, but we should have been furnished with a copy of their drainage regulations, in order that we might definitely advise. (3) If the Council have not provided storm-water sewers into which the drainage of private premises may be conveyed, we are of opinion that they will be unable to enforce the construction of duplicate drains to dwelling-houses.

Vacancies.

Assistant Engineer (Bath, January 29th).—For the Bath Union Workhouse. Salary, £25 a year, with board, lodging, and washing. Mr. J. Mannings, clerk, 3, North-parade, Bath.

Assistant Inspector of Nuisances (Eccles, January 31st).—For the Corporation. Salary, £65 per annum, rising by annual increments of £5 to £100. Mr. George William Bailey, town clerk, Town Hall, Eccles.

Buildings Inspector (Southend-on-Sea (February 2nd).—For the Corporation. Salary, £104 per annum. Mr. William Gregson, town clerk, Southend.

Clerk of Works (London, N., February 5th).—For the Edmonton School Board. Salary, £3 3s. per week. Mr. John Moule, clerk, School Board Offices, Upper Edmonton.

Clerk of Works (London, N.).—Salary, £3 per week. Mr. E. J. Lovegrove, engineer and surveyor, Hornsey District Council, Highgate.

Clerk of Works (Teignmouth, February 9th).—For the Urban District Council. Mr. C. Jones, surveyor and engineer to the Council, Town Hall, Teignmouth.

Electrical Engineer (Barrow-in-Furness, February 8th).—For the Corporation. Commencing salary £200 per annum. Chairman of the Electric Lighting Committee, Town Hall, Barrow-in-Furness.

Non-Poisonous. TRADE CAMPHYLENE MARK *Effective.*

FLEMING'S DISINFECTANTS

CHEAPEST AND BEST, SOLID, LIQUID, AND POWDER FORMS.

Fleming's Non-Corrosive, Stainless Camphylene Cream is unequalled for use in Hotels, Clubs, Public Conveniences, for Flushing Drains, Sewers, &c. &c. Supplied to a large number of Corporations, County Councils and other bodies throughout the United Kingdom.—Send for Samples and Quotations—

FLEMING'S OIL AND CHEMICAL CO., LTD.,

101, LEADENHALL STREET, LONDON, E.C.

Agents Wanted where not already represented.

ELECTRICAL ENGINEER (SOUTHEMD - ON - SEA, February 2nd).—For the Corporation of Southend. Salary £200, rising by annual increments of £25 to £300 per annum. Mr. W. Gregson, town clerk, Southend.

ENGINEER, &c. BURY (LANCS.), February 7th.—For the Gas Committee. Salary to commence at £350 per annum. Mr. John Haslam, town clerk, Corporation Offices, Bury.

ENGINEER AND SURVEYOR (DERBY, February 12th).—For the Corporation. Salary £600 per annum, increasing by £50 per annum to £750. Mr. H. F. Gadsby, town clerk, Town Hall, Derby.

INSPECTOR OF NUISANCES (WELLINGBOROUGH, February 2nd). — For the Urban District Council. Salary £80 per annum. Mr. J. T. Parker, clerk, 29, Church-street, Wellingborough.

Contracts Open.

The dates given below are the latest up to which tenders can be received.

BARROW-IN-FURNESS.—January 31st.—Sewering.—Mr. John Butler, architect, Cornwallis-street, Barrow.

GULLANE (SCOTLAND).—January 31st to February 5th.—Sewer.—Messrs. Belfrage and Carfrae, C.E., 1, Erskine-place, Edinburgh.

LONDON, W.—January 31st.—Electric Lighting.—Mr. A. Saxon Snell, F.R.I B.A., 22, Southampton-buildings, Chancery-lane, W.C.

TONG (YORKS).—January 31st.—Sewers.—Mr. James Smith, Oddy-street, Tong-street, Dudley Hill.

LONDON, N.W.—February 3rd.—Sewer.—The Surveyor, Vestry Hall, Hampstead.

DENTON (LANCS).—February 5th.—Sewerage Works.—Messrs. Lomax and Lomax, 11, Fold-street, Bolton.

HOUGHTON-LE-SPRING.—February 5th.—Removal of Refuse.—Mr. John Geo. Baty, clerk, District Council Offices, Houghton-le-Spring

LONDON, S.W.—February 9th.—Reconstruction of Drainage, &c.—Mr. T. W. Aldwincle, 1, Victoria-street, Westminster.

TIPPERARY.—February 14th.—Sanitary Works.—Mr. Joseph Gubbins, clerk, Workhouse, Tipperary.

BURNLEY. — February 16th. — Mr. S. Edmondson, district surveyor, 18, Nicholas-street, Burnley.

HORNCASTLE.—February 1st.—Precipitating Tank.—Mr. S. G. Overton, 2, Manor House-street, Horncastle.

To Surveyors, Sanitary Inspectors, &c.—First-class Cycles at reasonable prices. Don't place your orders elsewhere until you have seen our post-free catalogue.—MELROSE CYCLE COMPANY, Coventry.

INSURANCE.

SCHERING'S NEW DIETETIC.

This is a new albumen preparation for domestic use. Its constituents, similar to milk, especially Human Milk, give it a peculiar value.

SANOSE

SANOSE is an odourless and tasteless white powder, forming an emulsion when stirred in water. THE MEDICAL PROFESSION strongly recommends it in cases of Anæmia, Dyspeptic troubles, Consumption, and in Cachectic Women.

For literature see "THE THERAPIST," November, 1897, and January, 1898.

Price 1s. per ounce; 3s. 6d. per 4 ounces.

Apply to all Chemists and Druggists, or to **A. & M. ZIMMERMANN, 9-10, St. Mary-at-Hill, London, E.C.**

THE DRAINAGE OF VILLAGES.

BY

WILLIAM SPINKS, Assoc. M. Inst. C.E.,

Member of the Incorporated Association of Municipal and County Engineers; Member of Sanitary Institute Lecturer on Sanitary Engineering—Yorkshire College—Victoria University; President of Sanitary Engineering Section of the British Institute of Public Health, 1895.

SYNOPSIS OF CONTENTS.

PART I.—Statutory Powers—Pollution of Streams—In case of Failure to Provide Schemes—Existing Sewers—Present Means of Disposal—Composition of Sewage—Self-purifying Power of Rivers.

PART II.—Areas of District to be Sewered—Power to enter Private Lands—Works without District—Special Drainage Districts—Power to Agree with neighbouring Authority to take and deal with Sewage—Joint Sewerage Boards—Rainfall—The Geological Character of the District—Present and Prospective Number of Inhabitants—Supply of Water—Sanitary Appliances—Position of Outfall Works—Power to Purchase Lands—Borrowing Powers.

PART III.—Requirements of a Sewerage System—Depths—Gradients—Lines—Sewers and their Jointing—Manholes—Flushing—Ventilation.

PART IV.—Sewage Disposal—Purification through Land—Tanks—Sludge—Filtration.

The SANITARY PUBLISHING COMPANY, LTD., 5, Fetter Lane, LONDON, E.C.

Price 2s. 6d.; by Post, 2s. 9d.

A HEALTHY HOME.

By FRANCIS VACHER, F.R.C.S., M.R.C.P., M.O.H., Cheshire.

CONTENTS.

CHAPTER I.—**Introductory:**—Health of the Individual and Family—How shall they be Housed Wholesomely?

CHAPTER II.—**Site. Soil. Aspect:**—Desiderata as regards Site—Constituents of Soil—Ground Water—Rainfall—Diseases connected with Ground Water.

CHAPTER III.—**Building Materials.**

CHAPTER IV.—**Construction:**—Foundation—Walls—Damp Course—Damp-proof Coating—Thickness of Walls—Size of Floor Joists—Drain Pipes and Gutters—Height of Chimneys.

CHAPTER V.—**Design and General Arrangements.**

CHAPTER VI.—**Warming: Lighting and Ventilation.**

CHAPTER VII.—**Hot and Cold Water:**—Source of Supply—Pollution in Transit—Cisterns—Filtering—Service Pipes.

CHAPTER VIII.—**Sanitary Requisites:**—Drainage—House Drains—Drain Testing—Disconnecting from Sewers—Soil Pipe—Closets—Baths—Sinks—Grease and Gulley Traps.

CHAPTER IX.—**Decoration and Furniture.**

CHAPTER X.—**Stables, Cowsheds, &c.:**—Lighting and Ventilation—Drainage—Space required for each Cow.

CHAPTER XI.—**House Cleaning.**

CHAPTER XII.—**Obligations of Householder and Sanitary Authority:**—Right of Drainage into Public Sewers—Examination of Drains—Removal of Filth—Abatement of Nuisances.

THE WHOLE WELL ILLUSTRATED.

THE SANITARY PUBLISHING COMPANY, Limited, 5, Fetter Lane, London, E.C.

SITUATIONS.

VACANT.

☞ *Advertisements of Situations Vacant are inserted at the rate of Sixpence per line (prepaid), minimum three lines — eight words to line. Special rates for a series.*

WANTED

THE SANITARY RECORD *will be found an excellent medium for those who are desirous of seeking Situations in the Offices of Surveyors, Sanitary Inspectors, Sanitary Engineers, Architects, &c. The charge for such advertisements (prepaid) is Sixpence per line. Minimum three lines—eight words to the line.*

MUNICIPAL ENGINEERING, &c. — WANTED SECOND-HAND BOOKS relating to the above and allied subjects.—Particulars and post free prices to H. Mitchell, Acre Works, Wibsey, Bradford.

☞ **Advertisements for this Department must reach us by Tuesday morning in each week, at latest.**

SANITARY ASSOCIATION OF SCOTLAND.

EXAMINATIONS IN SANITARY SCIENCE.

Examinations for Certificates of Competency in Sanitary Science are held each year as follows, viz.:—In Glasgow in April, in Edinburgh in October, and at such other time and place as the Board of Examiners may determine.

Entrance Fee £2 2s.

For further particulars apply to

GEORGE MIDDLETON, M.A., LL.B.,
Writer, 92, Bath Street, Glasgow,
Secretary to the Board of Examiners.

A Stamped Addressed Envelope must accompany all letters requiring an answer.

SANITARY INSTITUTE EXAMINATIONS.

SPECIAL Corresponding Classes for the **Practical Sanitary Science,** and **Sanitary Inspectors' Examinations** of the **Sanitary Institute, 1897,** conducted by a gentleman holding appointments as Urban District Council Engineer and Sanitary Inspector, holder of three certificates from the Sanitary Institute, First-class Honour Medallist Hygiene, &c. Hundreds of successes.—For all particulars, testimonials, &c., apply Mem. San. Inst., Office of THE SANITARY RECORD, 5, Fetter-lane, London, E.C.

LIGHTING, HEATING, and COOKING.

A PRACTICAL TREATISE.

USEFUL TO EVERYBODY.

Price 6d.; by Post, 7d.

5, Fetter Lane, London, E.C.

OFFICIAL ADVERTISEMENTS.

THE SANITARY INSTITUTE.—LECTURES AND DEMONSTRATIONS FOR SANITARY OFFICERS.

The Twenty-fifth Course of Lectures will be held at the Parkes Museum, Margaret-street, W., on Mondays and Thursdays, commencing February 21st.

The Course includes, in addition to the Lectures, a number of Practical Demonstrations and Inspections at places illustrative of Sanitary Practice and Administration.

Full Particulars can be obtained at the offices of the Institute, Margaret-street, W.

SANITARY INSTITUTE EXAMINATIONS.

TUITION BY CORRESPONDENCE.

An Engineer and Surveyor (Mem. San. Inst.), Certificated Surveyor and Inspector, prepares students for these Exams. by Correspondence through the post.

Fees strictly moderate. Cramming studiously avoided.

The course of tuition is arranged so as not only to qualify the student for passing the exams., but what is of equal importance, viz., that he may become a thoroughly efficient Inspector.

On successfully passing the exams., all possible assistance and advice is given to help forward intending candidates for public offices.

Many of my old pupils are now filling positions with salaries of over £120 a year.

For terms, &c., address "C. E.," care SANITARY RECORD, 5. Fetter-lane, London, E.C.

THE

Sanitary Record,

FEBRUARY 4, 1898.

Notes.

THERE continues to be great and increasing attention paid to the discoveries made, and established in actual practice, within the past two years, that the purification of sewage, whether by land treatment or artificial filters, is dependent upon bacterial or, as it is also termed, biological action, and that it is only in a very minor degree chemical and mechanical. The systems which have been almost simultaneously developed at (1) Sutton, Surrey, of purifying sewage by passing it in its crude state through bacteria tanks constructed of coarse ballast, where the sludge is absorbed by bacterial action without cost in chemicals and sludge pressing; and (2) at Exeter on the septic tank system, where the crude sewage is passed through hermetically-sealed sewage tanks, and the sludge is absorbed by bacteria in a manner akin to the Sutton process, except that in the latter case the purification is effected by aërobic bacteria, while at Exeter it is effected by anaërobic bacteria, apparently attract the notice of Local Authorities who are desirous of a solution of the sewage disposal difficulty to an extraordinary degree.

WHILE we believe it is admitted that each system is successful in carrying out what is claimed for it, there is one point which does not appear to us to have had the attention which it deserves, viz., what is the relative cost of construction of works for the treatment of sewage for a given population, say 1000, on (1) the septic tank system as at Exeter, and (2) the bacteria tank system as at Sutton? From what we have been able to gather, the latter system requires no expensive engineering work, but that the filters may be and are constructed without artificial walls, and that it may be adopted anywhere and without payment of royalties, while under the Exeter system the cost of construction of tanks must be somewhat heavy, and being a patented process royalties will be payable to the patentees. It would be highly interesting if those concerned would furnish figures so as to enable Local Authorities to form an opinion as to the relative advantages and costs on a common basis of the systems in question, and we hope that this will be forthcoming.

A CRITIC of that part of Lord Rosebery's speech, to which we referred in our "Notes" last week, dealing with the larger views that are now taken by Municipal Authorities compared with those held a generation or two since, has justly pointed out that in making such a comparison we must be careful not to depreciate the importance of the work which has been done by our predecessors, or to overlook the fact that it would have been impossible for them, circumstanced as they were, to undertake enterprises of the nature that we are now facing, and for which we take such credit to ourselves. In the middle of the present century, and since the hands of our municipal fathers were quite full with important undertakings to introduce a sanitary *régime* into city life, modern sanitation had but just taken its rise, the new ideas took time to spread, and the task of our civic rulers then was to carry out these newly-recognised principles within the limits of their jurisdiction.

IT was a large task, and it cannot yet be said to be accomplished, for the perversity of human nature is a perennial factor to be reckoned with; and there is little hope of the day when dirt, and its concomitant disease, shall have ceased to exist. But much has undoubtedly been done, and for this our gratitude is due to the energy and the practical wisdom of our Local Authorities for the past

generation. Large improvement schemes, important drainage systems, extensive undertakings for water supply, together with the establishment of Health Departments in all our larger towns—these furnished work sufficient to engross the energies of the most energetic reformers. While so occupied it would have been impossible for them to think of such social reforms as picture galleries or museums for the people. "The sanitation of the mind as well as of the body" is an excellent precept, but the sanitation of the body comes first; and it was necessary that our cities should be cleansed physically before the higher claims could be attended to. We have reached a higher degree of development in that we are now able to attend to such claims; but it would be a mistake for us to forget that, had it not been for the work of those who have gone before us, we could never have reached our present stage.

The Duke of Devonshire received a deputation last week, introduced by Sir Henry Roscoe, with regard to the reorganisation of the University of London upon the lines of the report of the Cowper Commission. The deputation was composed of members of the Senate of the University of London, and representatives of teaching and scientific bodies, including many names of the highest eminence in their respective spheres. The unanimous opinion expressed was that the University should be remodelled on teaching lines, and that what has hitherto been merely an examining body should be reconstituted into a teaching university. The Duke of Devonshire, who evidently was in hearty sympathy with the objects of the deputations, assured them that the aid they had given him would be of great service in enabling him to urge on his colleagues and on Parliament the importance which was attached to the question by almost all those who were in any way connected with the teaching institutions of the metropolis. He thought that the delay which had thrown back the Bill of last year had had the advantage of removing most of the serious opposition, and a fair and just compromise between every shade of university opinion had been arrived at. There is, therefore, every prospect that this important measure will find a place in the coming session of Parliament.

It was announced a short time since that a generous but anonymous donor had been so moved by witnessing the spectacle in the present out-patients' department of the London Hospital that he had given the magnificent sum of £25,000, to be devoted to the building of a new department outside the hospital. Two conditions have been attached to the gift. One is that the out-patients should pay some small sum towards the cost, not of treatment, but of the medicine and bandages supplied; and the other is that hospital letters should be abolished for the future. Both of these reforms have commended themselves to many thoughtful observers. As for the first, it will diminish the pauperising tendency that generally results from the knowledge that the necessities of life can be had for nothing, and will add to the feeling of independence that should characterise the working classes. And at the same time additional care should be taken that our hospital system is not abused, as there is reason to fear that it sometimes is, by those who can afford to pay for medical attendance. Such cases are perhaps exceptional, but there is no doubt that they do occur occasionally; so that all doubtful applications should be carefully tested before gratuitous assistance is given. For it is not right that beds which have been provided for the poor should be occupied by those who are in fairly easy circumstances.

The other matter is perhaps of still greater importance. There is a growing feeling that the use of subscribers' lines is at variance with the principle which underlies all our hospital system. A hospital is supposed to be a charity, where people who are poor may have gratuitous medical attendance when sick. It is therefore felt to be an anomaly that a patient who is fortunate enough to possess an influential friend who is a subscriber should have a preference over those who are poor and ill, and without any such influence. And apart from this anomaly, it is unfortunately the case that subscribers' lines are a frequent source of friction between the subscribers and the management, for many people hold that if they pay so much a year, they are entitled to a *quid pro quo*—which, it is needless to observe, is inconsistent with the very idea of charity. In support of the present practice it is argued that, were it not for subscribers' lines, the subscriptions would show a serious falling off. Experience, however, shows that this is not necessarily the case, and many eminent authorities are now inclining to the view that it would be well that the system should be discontinued.

The distribution of the money received for 1897 for the Prince of Wales' Hospital Fund will at once be attended with beneficial results. The sums received from the sale of stamps, amounting to about £38 000, will be divided among such institutions as come under the classification of hospitals. The excellence of the idea of the hospital stamps has been proved by the handsome sum that has been received from this source. Then the annual subscriptions which have been promised, and the interest on investments, amounting to £22,050, will be divided among those hospitals where more than 100 beds are in constant occupation. By this means the most pressing wants of the larger hospitals are relieved for the present, and it is expected that in future the income of the fund will be sufficient to meet their requirements. The immediate result is that wards at Guy's, St. Thomas's, and other hospitals, which have been closed for want of funds, will at once be re-opened.

The statistics given by Sir Alexander Binnie, chief engineer to the London County Council, in his evidence before the Royal Commission on London Water Supply, which appeared in our "Notes" last week, are so bristling with large figures that to the mind unaccustomed to grasp the significance of numbers they are apt to be a little confusing. It is therefore satisfactory to know the practical deductions which a man of such experience has arrived at. Sir Alexander strongly advocates the placing of the London water supply in the control of the London County Council, less on the score of greater cheapness to the consumer than on the ground of public policy.

This conclusion is partly based on the experience of those large towns where the supply is managed by the Corporation. In Paris, for example, the daily consumption is 47·1 gallons per head of the population; in Glasgow it is 54·56 gallons per head; and in Buffalo, in the United States, it reaches the phenomenal figure of 325 gallons. The average daily consumption in London, on the other hand, is only 35 gallons per head, and that is most certainly not because the water is less needed.

The extraordinary outbreak of illness which has attacked many of the guests who attended the Warwick County Lunatic Asylum Ball at Hatton a fortnight ago, is at present surrounded with a good deal of mystery. At first it was given out by the Asylum Authorities that it was merely a violent outbreak of influenza, and it was officially reported that about forty persons, nurses and inmates in the institution, besides a number of attendants residing outside, were suffering from this malady. In addition to those connected with the asylum, however, a large number of those who were present at the ball have since been prostrated. They have been examined by their ordinary medical attendants, and their symptoms, it is said, point to some form of poisoning. The symptoms are reported to be nearly identical in all the cases, and include sickness, diarrhœa, and pains in the abdomen, and the conviction of the sufferers themselves is that they are suffering from poisoning and not from influenza. This belief receives support from the fact that the outbreak is confined exclusively to those who were present at the ball.

There is something strange in this conflict of medical opinion in a matter which one would have thought comparatively free from doubt. It is hard to understand how there should be any doubt as to whether the cases are cases of poisoning or not, though it may well be difficult to trace the outbreak to its origin. Notwithstanding the secrecy which is being observed by the authorities at the Asylum, the general opinion is that the cause must lie either in some fault in the food or in the cooking utensils, for it would appear that the influenza theory obtains no acceptance. In any case it is a matter which calls for strict inquiry. Mr. Wilmhurst, the Coroner for the district, is understood to have instructed special inquiries to be made by the police; an inquest will be held into the cause of the death of Mrs. Jones, the head nurse at the Asylum; the County Council are expected to take some action in the matter; and it is stated that the Home-office is taking steps to secure a careful investigation into the circumstances of the mysterious outbreak.

The anti-vaccinators who make their recalcitrancy a matter of principle have at least the courage of their opinions. Two gentlemen of a certain country town having been offered the alternatives of fine or imprisonment, have heroically accepted both punishments to seal their faith. They have paid, that is, the amounts of the fines and expenses to the treasurer of the local Anti-vaccination League, and at the same time they have, with much pomp and dignity, gone to prison, amid a chorus of congratulations from their sympathisers. But a better story still is chronicled of a certain clergyman who went to prison with two comrades the other day as a testimony to his convictions; and on the return of the martyrs from durance vile, they were honoured by their friends at a social gathering. The reverend gentleman, who was gifted with a humorous view of the situation, seems to have enjoyed his sojourn thoroughly. Never was he better treated in his life. The food was perfect, and his health apparently derived considerable benefit from the short confinement. And when we add that he was supplied with the writings of Mr. Andrew Lang and Professor Drummond, we can understand that the time was not unprofitably spent.

There are certain persons who take a delight in throwing out innuendoes on the conduct of public affairs by both local and national officials. In every village you will find some who are prepared to assert that the members of the Parish Council are "making a good thing" out of their serving upon so august a body. In larger districts others roundly proclaim that the affairs of the Urban or Town Councils are in a chaotic state, and that the finances especially are so muddled by the officers and committees that it is impossible to know whether the district is in a condition of solvency or hopeless bankruptcy. And, not content with these rash proclamations, they go on to denounce the officials as being susceptible to every form of corruption. As a rule these "knowing ones" usually confine their statements to generalities, and are careful to avoid specific charges. And should one of the accused meet them and challenge them to substantiate what they have affirmed, it is easy to discover they are entirely ignorant of the very matters of which they claim so complete a knowledge. Still their conduct often makes the lives of public men very uncomfortable, and arouses an atmospere of suspicion where there should be perfect trust and confidence.

But sometimes these charges against the honesty of public officers find their way into the press, and are made in such a manner as to cast a slur upon the integrity of large bodies of hard-working and conscientious men and women. Such an instance is before us as we write. Every week about a page of *Science Siftings* is devoted to "Queries and Answers." Some readers are supposed to propound questions, while others in their turn supply the answers. In the last issue one of the queries is "Why is London unhealthy?" Before dealing with the reply, we may say at once that the interrogation implies a state of our great metropolis which cannot be sustained. Broadly speaking, London is not unhealthy, as is demonstrated week by week in the returns of the Registrar-General. Compared with the other large towns, our capital city has no reason to be ashamed of its position in that list. That some neighbourhoods are little better than "death-traps" we readily admit, but to assert the "whole" is "unhealthy" displays a lack of knowledge altogether inexcusable. And the untenable prejudgment of the question contaminates the individual who professes to supply the answer.

He claims an acquaintance with the slums; he has dived into their worst recesses, and because in these he has discovered some "filth diseases," he proclaims, with all the pomposity of superior wisdom, that the metropolis is as bad as the queriest paints it.

If he had stopped here, no great harm would have been done, because after all he graciously informs the readers that this is "his private belief." Happily the country is free, and he may indulge in "private beliefs" to his heart's content. But when he goes on to level charges of dishonesty against the Sanitary Inspectors of the London County Council, the bounds of privacy are overstepped. He asserts that "the best-founded complaints as to the condition of an ill-drained tenement house may be rendered quite ineffective by 'tips' to the 'Inspector' of from 10s. to £1 per complaint. Poor and comparatively ignorant folks are helpless under such conditions of affairs. They realise the evil of insanitation; but they recognise the uselessness of invoking a corrupt maladministration of supposed sanitary law." For anyone to indite so base an insinuation against a respectable body of public servants is, to say the least of it, cowardly and despicable. No wonder the editor of the paper desires to dissociate himself from the "private belief" of his valued correspondent; but we venture to think that before he allowed such a sweeping accusation to appear in his pages he should have demanded some proof of their truthfulness. If this is not forthcoming, then he should decline to be a party to their propagation.

This "self-satisfied slummer" may have traversed some of the dark corners of the metropolis, but we question if he has the slightest knowledge of the rules and practices governing local administrative bodies and their officers; and we venture to assert there is no more conscientious worker among public health officials than the Sanitary Inspector. His duties are often unpleasant, and, added to this, he knows that in the minds of some there is an unreasonable prejudice against him; but this does not make him shrink from the performance of his duty. And to imply that he is prepared to sell his character, his prospects of advancement, and to risk his situation for a few paltry pieces of silver, is a wicked libel. That occasionally there may be found a "black sheep" is possible, but the whole body should not be condemned because one member is false to his trust. We challenge this anonymous assailant to produce evidence to substantiate his case; and until this is done we protest against such statements being circulated, even in a limited circle.

Our readers will remember that, some few weeks ago, considerable stir was occasioned by the statements appearing in a daily contemporary concerning the condition of the river Brent. The Urban District Council of Hanwell does not appear to have inquired very closely into the cause of the pollution, but forwarded a complaint to the Middlesex County Council, implying that the blame rested with it. Naturally the Council at once appointed a Special Committee to investigate the matter, and at the quarterly meeting held last week, this Committee presented its report. It was stated that samples of the water were taken, and a special examination was made, with the result that the pollution was traced to the sewage farm of the persons complaining, namely, the Hanwell Urban District Council, and they had instructed the solicitor to serve the Council with notice to abate the nuisance. The Urban Council must be sorry now that it did not make a fuller examination before fixing the blame elsewhere.

A significant report on aniline dyes in food has just been made to the Marylebone Vestry by Dr. Wynter Blyth, in which he emphasises the necessity for a reform in the laws governing our food supply. Dr. Blyth warns the members of the vestry that "the aniline dyes possess such great tinctorial power that even with those that are poisonous, the quantity taken in the consumption of any one ordinary coloured article is most minute, so that in few cases could decided symptoms be produced. On the other hand, when sugar, butter, milk, cream, sausages, confectionery, and a number of other things all have a small trace of analine, these traces in the day total up. Observation and experiment have shown that the aniline dyes in small doses interfere with digestion." Dr. Blyth states that it is his opinion that the increase of maladies of the digestive organs which has been noted of late is, in part, due to the increasing use of aniline or tar colours, and to the use of antiseptics such as boracic acid, formalin, and salicylic acid in foods. In conclusion he urges the necessity of its being made an offence to use aniline dyes for colouring foods unless the purchaser is informed of the fact. This recommendation, we are assured, will be endorsed by all analysts.

On another page we give some interesting details concerning a visit paid to Leyton for the purpose of inspecting the new refuse destructor. As Mr. W. H. Maxwell, Assistant Surveyor, Leyton, will shortly give an illustrated description of the destructor in question in the course of his very able articles dealing with destructors in general, now appearing in our columns, we have not gone into the matter in connection with this particular function—a most gratifying one to all concerned, by the way, and an occasion which showed the public spirit of Leyton at its best.

TO OUR READERS.

The Editor solicits the co-operation of readers in making The Sanitary Record *more attractive by means of pen-and-ink sketches, photographs, and diagrams. There are many phases of sanitary work which lend themselves admirably to illustration. By this means not only individual articles, but the journal as a whole will be heightened.*

THE SANITATION OF DOMESTIC BUILDINGS.

By Frank Latham, C.E., M. San. Inst, &c., Assistant Surveyor, Borough of Margate.

CHAPTER II. (*continued*).

Section 3.

The question of soil pipes is as important a part, if not more so, as any portion appertaining to the house drainage system, both as regards material and workmanship. It is a great mistake on the score of economy to use cheap soil pipes. These are cheap, perhaps, to the builder, but dear, to say the least of it, to the owners and occupiers, especially when they involve sickness and consequential trouble and expense.

The best material for soil pipes is drawn lead, weighing not less than 8 lb. to the superficial foot.

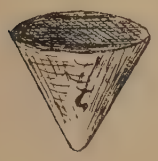

Fig. 15.

Cast and seamed lead pipes should not be used for any drain purposes, they being subject to pinholes and other weaknesses, and therefore not to be depended on, besides which they will not stand bending.

The advantages of drawn lead pipes are that they are smoother and less absorbent than other pipes, conducing to cleanliness and the reduction of fouling to a minimum, they are also more reliable and durable, being less affected by the weather. They are less cumbersome, and can be bent into any position required.

The wiped joint is the strongest and best for all lead pipes. It is no easy matter to make a satisfactory joint of this description; on the contrary, it requires a large amount of skill and experience on the part of the plumber before he succeeds in mastering this difficult part of his craft, and it naturally follows that such work, if required good, must be well paid for. In the first place there must be a socket and spigot for one pipe to fit into the other, as in the case of drain pipes, but in this instance such sockets have to be formed by the plumber at the end of the pipe, instead of these being ready made by the manufacturer. This part of the work is of all importance in order that no part of the pipe or joint should be weakened, and that no solder can gain access through the joint into the interior of the pipe.

Fig. 16.

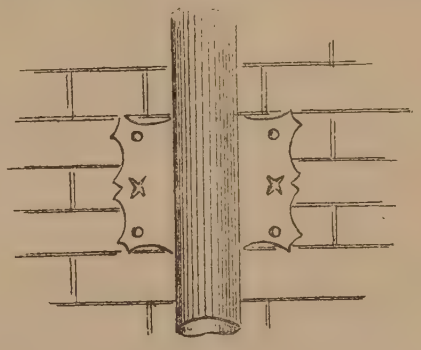
Fig. 17.

The best way to obviate such defects is to form the socket by opening the end of the one with a wooden tan pin (Fig. 15) to a sufficient width to receive the spigot end of the other pipe, which should also be treated slightly in a similar manner, with the outer edge rasped off till very thin in order to make it take its bearing and become a true fit with the interior of the socket. This being done, any grease that may exist should be removed, and the ends painted a few inches up the external and internal surfaces, with a mixture of vegetable black or lamp black, glue, and dried chalk or whiting, and upon its becoming dry the external surfaces of both socket and spigot for an inch or two, according to the size of the pipe, together with a small portion round the inside of the former, should be shaved with a shaving-hook (Fig. 16), removing the paint and a very thin portion of lead, leaving them perfectly bright; to prevent tarnish, tallow should be rubbed over these bright parts. After the pipes have been properly adjusted, the solder, which is attended to by the plumber's mate, whose duty it is to see that it does not become overheated, consisting of one part of tin to three parts of lead, is now applied, being poured round the shaved portions of the pipes. The joint is then wiped into shape by means of a thick soldering cloth, which consists, as a rule, of moleskin well greased on the surface with tallow (Fig. 17).

Fig.

Plumbers wipe as many of their joints as possible in the workshop, but there are cases where upright joints have to be made. In these cases, to prevent waste of the surplus solder while making the joint, which would otherwise fall to the ground, a lead collar, well soiled, should be fastened round the soiled part of the pipe just below the joint (Fig. 18). This will catch the solder, which upon cooling can be easily removed.

Next to the wiped joint, but a long way from being near it as regards perfection, stands the blown joint and the copper bit joint, neither of which, in



Fig

these days of high sanitation, should be used. Good plumbers, as a matter of fact, will not adopt them for sanitary purposes. They consist, in the first instance, of the lower end of the top pipe being thrust into the upper end of the lower in a similar manner to that of the wiped joint, only to a greater depth. This being done in the case of the blown joint, the part where the joint is required to be made is heated by means of a flame blown against it by a blow-pipe, and a stick of solder is heated by the flame and run all round the joint till the socket is filled. The copper bit joint, which is inferior to the former, is made by a stick of solder

being melted into the space between the spigot and socket by means of a heated soldering iron, which has a copper end or bit. The solder for these joints consists of more tin than that used for wiped joints.

It is a mistake to use soil pipes of too large a diameter, as they only afford additional surface to become foul, and are not so self-cleansing by the action of the flush as smaller ones, and, further, they are more cumbersome and costly. As a rule, 3 or 3½in. lead soil pipes are sufficient for general purposes.

All soil pipes should be fixed outside the house

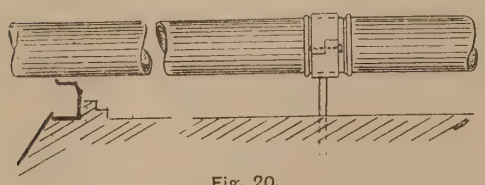


Fig. 20.

wall in the external air, as it must be remembered that the house drains, to a great extent, ventilate through the soil pipe; and should it be defective through age or accident the foul air would, in most cases, simply pass out into the open atmosphere, but if fixed inside such air would be introduced into the dwelling, thus setting up a dangerous nuisance.

The proper manner to fix lead pipes is by lead tacks, which are plates of lead, about 8in. long and

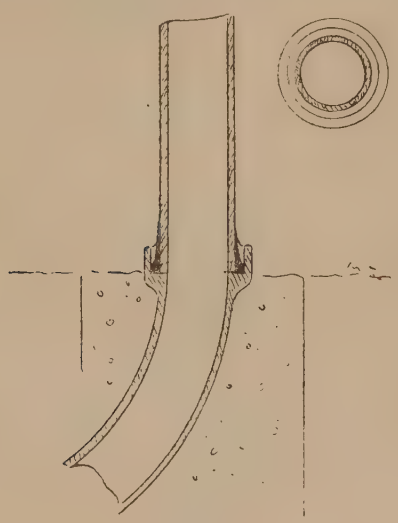

Fig. 21.

4in. wide, soldered on to the back of the pipe. These plates should be made of good stout lead, not less than 8 lb. to the superficial foot, which is very necessary when the weight of the pipe to be fixed is reckoned. These tacks should be put on the pipes in pairs, one pair for every six feet, and fastened to the wall by two large-headed galvanized iron wall-nails to each tack. (Fig. 19.)

The best position for soil pipes is facing south, where they will not be so much affected by frost and cold, which eventually affects the wear of the lead; and, further, a warm pipe increases the ventilating velocity. They should also be sheltered as much as possible in the nook between the walls of the house and back addition, but at the same time should have as few angles and curves in their course as possible, as not only do angles impede the flush, but also the ventilation, and cause extra wear and tear.

The connection between the lead soil pipe and the drain should not be by merely thrusting the foot into the stoneware or iron bend as far as it will go and then filling in the joint with cement, but the lead pipe should be slightly opened, bell-shape at the end so as to fit the socket of the bend, and then the joint properly cemented and made tight; or, what is better, a circular brass collar can be soldered round the end of the pipe, and extend three or four inches up the sides, being slightly thicker at the base, which will allow a firmer joint to be made in cement or lead. (Fig. 20.)

Iron soil pipes are much used, they being cheaper than lead, and if the work is well done are almost as successful. The too common practice amongst plumbers of using ordinary rain-water pipes jointed with red lead or putty is to be condemned, as not only are the joints insufficient, but the pipes being not intended for such purposes are much too flimsy to stand a proper test, or to be safely caulked.

When iron pipes are used they should be heavy soil pipes in 6ft. or 9ft. lengths, and not less than $\frac{5}{16}$in. in thickness, with good deep sockets, not less than 4in., and fixed against the wall with proper iron collars fastened round the sockets and secured by means of arm pieces into brickwork. (Fig. 21.) The spigots should be provided with a bead all round to fit easily into the socket, and after a few strands of gasket have been carefully forced between spigot and socket, the latter being upwards, the remaining depth of the joint should be made with melted lead and then finished with a caulking tool, at the same time taking care not to overdo it and split the pipes. All iron soil pipes should be coated inside with some special process to prevent corrosion and to preserve the metal, such as with Dr. Angus Smith's solution, or painted with Blundell's petrifying liquid, or three coats of oxide, or glass-lined.

Galvanised iron pipes are much used for this purpose, but they also require special inside treatment, as it is found that the surfaces undergo rapid deterioration under the action of sewage. Galvanising consists of covering the iron with a thin coating of zinc by placing the heated pipes in a bath of chloride of zinc and afterwards into melted zinc and cooling off.

NOTE.—The Fig. marked A in issue of 21st inst. should have been part of Fig. D, and the Fig. marked Fitzpatrick's Joint should have been marked A.

Sanitary Congress and Health Exhibition, Birmingham.—The Sanitary Institute has accepted an invitation from the Council of the City of Birmingham to hold its next Congress and Exhibition of Sanitary Appliances, Articles and Manufactures connected with health in that city, commencing September 19th, 1898. Full particulars as to space, &c., in the Exhibition will be ready shortly, and can be obtained on application to Mr. E. White Wallis, secretary of the Institute.

NOTES ON
PRACTICAL SANITARY SCIENCE.

By WILLIAM H. MAXWELL.

Assistant Engineer and Surveyor, Leyton Urban District Council, Author of "Drainage Work and Sanitary Fittings," "Ventilation, Heating, and Lighting," &c., Certificates of the Association of Municipal and County Engineers, and Sanitary Institute.

No. 47.—REFUSE DESTRUCTORS.

(Continued from page 89.)

At Oldham a series of experiments carried out by Mr. Watson showed that the average temperature of the mattress chamber through which the hot gases pass on their way to the boiler was found to be 2019 deg. Fah., the minimum being 1654 deg. Fah., and the maximum 2346 deg. Fah. The above results are confirmed by the melting of three pieces of cast iron, of which the melting point was not less than 2100 deg. Fah., in one of the fires.

For taking the temperatures, the following apparatus on the principle of the "*method of mixtures*"[121] was used. An ordinary iron bucket was cased all over with about 2in. of slag wool or silicate cotton, the cover for the top being movable. A thermometer was hung over the side of the bucket, dipping into about two gallons of water, less or more, weighed for each experiment. Pieces of wrought iron from 4½ lb. to 5½ lb. weight were used, and it was found that the loss of weight by oxidation was negligible even for several successive experiments with the same piece. The loss of heat by radiation from the bucket was also negligible, being at 120 deg. Fah., only 1 deg. in 15 minutes; whereas the maximum temperature of the water, after the hot iron was put into it, was reached in less than five minutes. The method of using the instrument, as is well known, is to place a piece of metal (iron in this case, whose specific heat was taken at 1255) of known weight and specific gravity in the gases whose temperature is to be measured, and, when it has had time to reach the same temperature as the gases, to withdraw it and quickly place it in water of a known weight. The amount by which the temperature rises is a measure of the temperature of the iron before being placed in it.

The temperature of the gases as they escaped from the boiler flues was also measured, and found to be something over 855 deg. Fah.

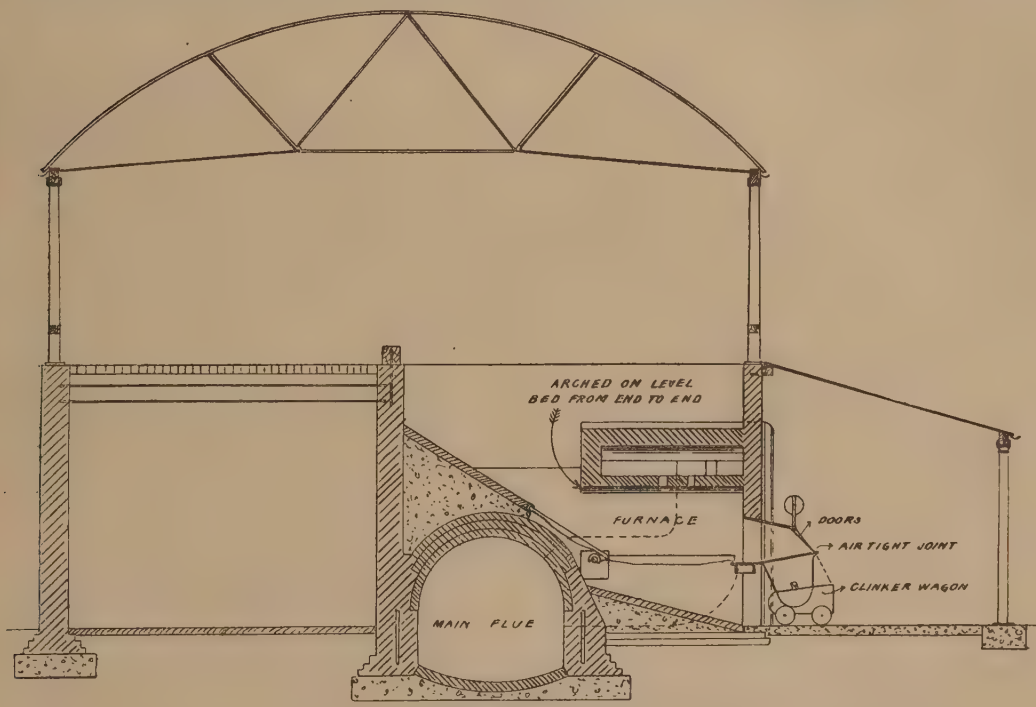

Fig. 11.—Section of one form of Healey's Destructor.

At Oldham steam is generated by the surplus heat in a Lancashire boiler, and 15-indicated horse-power is said to be obtained from each cell. The power thus generated is utilised in working two mortar mills, to supply power to the horses and provender department and a portion of the electric lighting station, and to produce the forced draught through the furnaces. Each furnace, it is stated, consumes over 8 tons per 24 hours as an average as shown by actual weighing, and as much as 8 tons 16 cwt.[122] per cell per 24 hours has been consumed. The residuum (including clinker and fine ash) of the bulk dealt with is given at 33 per cent. There is no demand for the clinker and ashes as such, but there is said to be a "ready sale for the mortar produced from the clinkers at 5s. per ton; also, successful experiments have

[121] *Vide* paper by Professor W. C. Roberts-Austen, C.B., F.R.S. "Proceedings" Inst. Civil Engineers, vol. cx., page 152.

[122] *Vide The Surveyor*, April 2nd, 1897.

been made in converting the clinker into paving blocks."[123]

Mr. C. Estcourt, F.C.S., F.I.C., Public Analyst to the City of Manchester, having analysed samples of clinker and gases resulting from the burning of ashbin refuse, garbage, &c., taken by him during the ordinary course of working at the Oldham destructor, reported[124] the results as extremely satisfactory, showing what a powerful effect the steam draught has upon the combustion. He states that "the carbonic acid without steam on is only 2 per cent., while with steam half on it is 9 per cent., and with steam full on it is 14·5 per cent., proving that the steam draught has the effect of getting full value out of the air that is used. The clinker is so burned that practically there is nothing combustible left therein; it may be tipped in a heap when hot from the furnace without fear of further combustion taking place. Further, no nuisance could arise from a heap of such clinker, either hot or cold. The analyses of the gases taken from the destructor furnace and the flues show that the combustion is practically perfect. No malodorous vapours can possibly escape. This is largely attributable to the action of the steam jet forced-draught apparatus, combined with the other arrangements of the furnace which ensure that only the proper quantity of air is admitted to the furnace. The steam, in passing through the incandescent fuel on the grate, is decomposed in such a manner as to assist in the formation of water-gas. The gases passing from the chimney are remarkably free from dust. The waste gases could not possibly cause a nuisance, or any injury to vegetation in the neighbourhood of the destructor, and in my (Mr. Estcourt's) opinion there is no necessity for a chimney more than 50ft. high to carry them off. The gases are completely cremated, the furnace being designed on thoroughly scientific principles."

The analysis of gases taken from the furnaces burning with full steam on is as follows:—

	Per cent.
Carbonic and sulphurous acids	14 6
Oxygen	5·4
Nitrogen	80 0
	100 0

The Horsfall Refuse Furnace Company also have a smaller type of this destructor, styled the "*Hospital Destructor*," which is stated to be capable of destroying about two or three tons of the most offensive material in a 12-hour working day. The furnace is used for rendering innocuous infected bedding, clothing, excreta, or any other offensive or dangerous material as garbage and refuse. A destructor of this kind has been supplied to the Joint Hospital Committee of the Blaby and Wigston Isolation Hospital.

Healey's Destructor.

A distinguishing feature in connection with this furnace,[125] one form of which is shown in Fig. 11, is the arrangement of flues whereby the gases from one furnace have to pass over the bright fire of another in a more forward state of combustion before escaping. The furnaces are worked in pairs, and the gases alternately made to pass from one to the other by means of dampers. The provision of a movable drying floor over the furnace is also made, upon which the charge is allowed to rest until it is thoroughly dried. The floor is then allowed to fall and drop it on to the grate.

The refuse is fed on to forward motion fire-bars, and in one form of this furnace the bars have also a slow wave-like motion imparted to them by means of a cam action worked by a special and simple steam or water motor, thus slowly moving the burning refuse towards the furnace doors, where it can be received into an iron trolley or barrow fixed to the furnace door, so that no fumes or heat can escape. Over the furnace is a reverberatory arch provided with openings communicating with a flue, which itself joins the main flue under the back of the furnace; the communicating flue being constructed in the thickness of the division walls separating the cells. A forced blast is also provided, if thought necessary, to increase the combustion.

A furnace called Fryer's and Healey's destructor was erected at Bradford, and in a paper read by Mr. C. Jones in 1887, at a meeting of Municipal Engineers at Leicester it is referred to in the following terms:—"The arches and furnaces were like Fryer's, and, following in the steps of previous inventors, he (Mr. Healey) attempted to purify the gases. The main arch was constructed hollow over the top and the gases made to pass at the back of each cell down the sides and over the arches, and the high temperature of the arches and flues were to have destroyed the offensive gases." The fumes and smoke of the Southfield-lane Destructor, Bradford, are now passed through a "Fume Cremator."

REFUSE DISPOSAL AT LEYTON.

AN INTERESTING FUNCTION.

At the invitation of the Leyton Urban Council about two hundred municipal engineers and surveyors, and chairmen of vestries and councils throughout London and the provinces, visited the borough on Thursday, 27th ult., to inspect the refuse destructor recently erected by Messrs. Beaman and Deas. Much interest was evidenced in the function, not the least interesting feature of which was the presence of that veteran sanitarian, Sir Douglas Galton, K.C.B., Chairman of the Committee and Past President of the Sanitary Institute.

The visitors subsequently sat down to a *recherché* lunch at the Town Hall, at which Mr. C. G. Musgrave, Chairman of the Council, presided.

Mr. J. Trumble, Chairman of the Sanitary Committee, proposed the health of their chief visitor, Sir Douglas Galton. He alluded to the difficulty experienced in Leyton in the disposal of the sewage until they adopted the present system. After twelve months' working he thought it was due to the inventors that they should tell their friends all over the country that they had solved the problem.

123 *Oldham Evening Chronicle*, May 14th, 1896.
124 March 27th, 1896.
125 Mr. Healey has obtained numerous patents for destructor furnaces and arrangements connected therewith. The following may be mentioned for reference:—No. 2369 (1880); No. 5203 (1882); No. 10,035 (1884); No. 7703 (1885); No. 9342 (1886); No. 177 (1888); No. 1005 (1892); No. 8249 (1892); No. 12 990 (1892); No. 18,398 (1892); Nos. 6688 and 13,105 (1893); No. 12,179 (1894); and No. 14,598 (1896).

Sir DOUGLAS GALTON, in reply, said that at every moment of their existence they were throwing off disused matter in some shape which, if left in the vicinity, immediately turned into some form of poison. It was this refuse which, when scavenging was unknown, and when narrow streets and overcrowded houses were the rule in English towns, caused the plague to desolate their population. It was from similar causes that the vast centres of population in India were now suffering from the plague. They removed their liquid refuse from large towns by underground rivers and streams. In London the network of these under their streets was as great a marvel as the houses and palaces above ground. Until recently they had turned their sewage into the sea, or classified it by mixture with some substance which caused the solid part to be deposited. The deposit had to be disposed of. It was not sufficiently rich as a manure to bear the cost of conveyance to any distance by farmers, and within recent years London had incurred a charge of £100,000 a year to get rid of it by putting it into barges, from which it was dropped into the sea. That seemed to him a wasteful process, although his friend, the late Professor Huxley, used to say that a great abundance of fish in and near the estuary of the Thames was due to London sewage. (Laughter.) Here at Leyton, with the assistance of Messrs. Beaman and Deas, they had done much better than London. (Applause.) They had obtained a destructor, which dealt in a marvellous way with the refuse sludge. For after removing it from the tanks they in Leyton had only to squeeze it thoroughly and throw it into the furnaces, and then the heat from the perfect combustion, assisted in working the necessary machinery, and the clarified effluent passed into the river. But the burning of refuse, although it was hygienic, was an absolute waste unless they could devise some method of making use of the heat. A destructor should possess three qualities; it should burn up perfectly the refuse put into it without preliminary treatment, it should admit no deleterious fumes or smells, and it should supply heat to perform some useful operation. (Applause). In the Beaman and Deas destructor, with ordinary refuse a minimum temperature of 2000 deg. Fah. was maintained in the common combustion chamber, and he was informed that a pair of cells could consume fifty tons of refuse per day. This large consumption was accomplished because of the use of forced draught. It was to the skilful application of forced blast in this destructor that it owed its consistent high temperature in the combustion chamber and the complete combustion of the refuse. There were other peculiarities about the destructor which afforded most interesting subjects of speculation to the engineer, but these details would lead him too far. He must offer his congratulations to the town of Leyton upon the excellence of their sanitary administration, under which they had obtained so efficient a method of dealing with their refuse. They burned the whole of the solid refuse which resulted either from their sewage, their slaughter-houses, their streets, or their houses. They produced from it an innocuous clinker, a material which helped in the formation of the roads and footpaths, and they generated a large amount of heat, part of which worked their machinery, but very much now went to waste. He trusted this now wasted heat would soon be applied to some useful purpose—either upon the German plan in obtaining pure fat and gelatine from the offal of the slaughter-houses, or assisting in the lighting of the town by electricity, and in the drawing of the tramcars. It had occurred to him whether, seeing they had made such admirable progress in the disposal of this class of refuse, they might not progress a little further in the direction of what he might call more advanced hygiene. He had noticed that in the vicinity of the destructor there was an isolation hospital. It was a most desirable thing that persons dying of an infectious disease should be cremated. He hoped he should not wound their susceptibilities by his suggestion, but might they not provide on a similar system for the hygienic disposal of the dead? They who were advanced sanitarians looked upon the day as not far distant when, with their increasing population, cremation would largely prevail over the country, and he hoped he did not shock them too much by suggesting that their installation here might be usefully supplemented by the most hygienic adjunct—a crematorium.

Mr. MUSGRAVE said, as they all knew, Leyton immediately adjoined the metropolis, and therefore they had to deal with their own sludge. In 1881 the census showed that the population of Leyton was 26,000; in 1891 it was 63,000; and to-day it was between 90,000 and 100,000. He proceeded to speak of the difficulty of dealing with the sewage of this increasing population, and said a Committee of the Council travelled and saw every destructor in operation in England. They saw those that professed to destroy refuse and sludge, but they saw none dealing as they now dealt with theirs, and it was safe to say there were none dealing with the refuse and sludge as they did. (Hear, hear.) As public men they knew the difficulty of making a Council adopt a principle for which there was no precedent. However, thanks to their Surveyor, they decided upon this, and he would just read a recent report of the Surveyor:—"Since the last meeting of the Committee, four weeks ago, we have consumed 794 tons 4 cwt. 1 qr. of house refuse, and 530 tons 3 cwt. 3 qr. of pressed sludge, making a total of 1324 tons 8 cwt. in four weeks, or 16½ tons per cell per twenty-four hours." The destructor had done more than Messrs. Beaman and Deas had guaranteed it to do. That being so, he was perfectly satisfied, and the Council were also perfectly satisfied. He asked them to drink to the continued success of the Leyton destructor, and to Messrs. Beaman and Deas, the inventors.

Colonel SHARRATT replied. On behalf of his co-directors and himself, he was very pleased to have the opportunity of thanking the members of the District Council, and in so doing he would like to mention the names of Mr. Trumble, the Chairman of the Sanitary Committee, and Mr. Dawson, the Surveyor, for their courteous manner and ready appreciation during the erection of the works and since the opening.

Mr. SHARRATT proposed "The Chairman and Members of the District Council," to which Mr. MUSGRAVE replied.

Mr. BARE proposed "The Health, Prosperity, and Success of the Engineers and Surveyors," to which Mr. LEWIS ANGELL, Mr. DAWSON, and Mr. JOHN ANGELL replied.

The CHAIRMAN proposed "The Visitors," for whom Major FLOWER, Lea Conservancy, and Professor ROBINSON replied.

THE SANITARY INSTITUTE.

(Model Answers to Questions set at the Examination in Practical Sanitary Science held at Bristol, July 2nd and 3rd, 1897.)

(Continued from page 720)

Question 5.—What are the chief causes of contamination of the subsoil of dwellings, and how can they be avoided?

Answer.—The subsoil of dwellings erected on disused refuse tips is fouled by organic matter of both animal and vegetable origin and by the gaseous products of the decomposition of such matter. The Model Bye-laws of the Local Government Board direct that no such site should be built on until all filth is removed by excavation or otherwise. The annotated edition gives three years as the period in which such sites will become harmless by natural agencies, but most sanitarians say that many years may elapse before such a site can be safely used, and many would object to its being built on at all.

In old cities the whole subsoil is discoloured and offensive from various sources of pollution, as leakage from sewers, drains, and cesspools, escapes of gas from the mains, &c. Such a subsoil cannot be cleansed, but evil results of gaseous emanations may be avoided by a layer of good Portland cement concrete with a covering of asphalt over the whole site, by proper damp courses both over footings of basement and cellar walls, and just above ground level, and by building all basement walls hollow or with a dry area. Subsoil around a dwelling, and—by the diffusion of gases—under the dwelling may be contaminated by leakage from drains, privies, cesspools, soakage from pigsties, farm middens, &c., near the house. Also by soakage from unpaved back yards, on which filth falls or is thrown and gets washed in by rain falling directly thereon, or from the roof. These evils may be prevented, in the case of new buildings, by the precautions already mentioned: by paving all surfaces likely to be fouled, by testing all new drains by hydraulic pressure, by keeping all places for storing of filth of all sorts at a distance from the house and constructing them water-tight.

Question 6.—Describe the properties and uses of the following materials:—Portland cement, lias lime, chalk lime, hair mortar, asphalt, sandstone, oolite, and granite.

Answer.—Portland cement—an artificial cement, manufactured from chalk and clay, intimately mixed, burnt to a clinker, and ground very fine, has the property of setting under water and in other positions deprived of free contact with atmospheric air—should be grey or greenish grey in colour, weight about 112 lb. to the bushel, and pass through a sieve with 2500 meshes to the inch. Used in sanitary work for concrete; under-footings, over site of house, for fireproof and other floors, &c. Also for jointing drain pipes, and in the construction of ashpits, cesspools, &c.

Chalk lime.—Chalk is a nearly pure carbonate of lime, the white chalk being the purer, produces a fat lime, slaking violently when watered. Its "setting" properties are very poor, it is therefore unfit for use in masonry where strength is required. It is used for ordinary plastering on the ground of economy, because it can be thoroughly slaked, and on account of its porosity a doubtful advantage.

Asphalt is a combination of bitumen with calcareous matter, natural or artificial. It is impervious to water, nearly impervious to air, fireproof, and has some elasticity. It is used for damp courses, floors, pavements, and many other purposes.

Oolite.—A class of free stones, composed almost wholly of carbonate of lime. The well-known Portland, Bath, Chilmark, and Caen stones are oolites. The characteristics of oolite vary largely in different quarries and in different beds in the same quarries. Some of the Portland stone will stand exposure to the weather, and is useful for ashlar masonry; other varieties are good only for inside work; some of the softer kinds are excellent for carving for internal work.

Lias lime consists of carbonate of lime with more or less clay and other ingredients. The stone is dark blue before burning, and of a grey colour afterwards. It slakes slowly. Possessing hydraulic properties in a greater or less degree, it makes good mortar for ordinary building work.

Hair mortar.—A mixture of fat lime mortar, with hair, used for first plaster coats of walls and ceilings. The hair is used to give it cohesion.

Sandstone consists of grains of quartz (or occasionally carbonate of lime) cemented together by silica, carbonate of lime, magnesia, alum, oxide of iron, &c. Colour varies greatly, the variation being due to various combinations of iron. Sandstones are classified as flagstones, tiles stones, free stones and grits, the three first being useful for the purposes their names denote—the latter obtainable in large blocks, and being very hard and strong is useful for engineering works. Granite, properly so-called, consists of crystals of quartz and felspar and scaly mica. It has great strength, is hard and durable, and is used principally for heavy engineering works, for road setts and road metal.

Question 7.—What powers have a Rural Sanitary Authority to make bye-laws, and in respect to what nuisances are these limited?

Answer.—A Rural Authority may make bye-laws for the following purposes:—

Scavenging.—The cleansing of footways, removal of house refuse, cleansing of sanitary conveniences.

Common lodging-houses.—Prevention of overcrowding, cleanliness, and ventilation; precautions against spread of infectious diseases, &c.

Houses let in lodgings.—Purposes similar to the last.

Hop pickers.—Securing decent lodgings and accommodation.

Fruit pickers.—Same purposes as last.

New buildings.—Treatment of foul sites, drainage ventilation, and air space, structure of sanitary conveniences, &c.

Water-closets.—Ensuring provision of water for flushing.

Prevention of improper alterations to buildings constructed under Building Bye-laws.

Temporary dwellings (tents, vans, sheds &c.).—For promoting cleanliness and habitable condition; for prevention of spread of infectious disease; For prevention of nuisances.

Mortuaries (with respect to management of.)—

The Local Government Board may confer upon Rural Councils the powers of Urban Councils for the purpose of making bye-laws in respect of the following matters.

Nuisances.—For the prevention of nuisances arising from snow, filth, dust, ashes and rubbish, and from the keeping of animals. Save that as regards the keeping of animals, a Rural Authority cannot prescribe distance of pigsties from dwellings.

Slaughter-houses.—In respect of prevention of cruelty, cleanliness, drainage, ventilation, removal of garbage, water supply, &c.

Offensive trades.—With reference to prevention of nuisance from effluvia where materials are treated by heat, prevention of nuisance from storage of materials, and from retention of waste matters on premises, drainage, cleanliness, periodical lime-washing, &c.

New streets.—With respect to level, width, and construction, and as to sewerage.

New streets.—Provision of secondary means of access for removal of house refuse.

Public sanitary conveniences.—Prevention of improper use of.

Paving of yards.—Compelling owners to pave insanitary yards.

Removal of filth along streets.—For restricting removal to certain hours.

Powers as to making "regulations" for various purposes and powers derived from County Council in respect of Bye-laws for Lodging-houses for the Labouring Classes appear to be beyond the scope of the question set.

Question 8.— Describe the proper construction and fitting of a valve water-closet, and a short hopper closet, detailing the manner in which the water should be supplied and the way in which the discharge pipes should be dealt with.

Answer.—The valve closet consists of a hemispherical glazed stoneware basin, with a hollow rim to flush all parts of surface of basin equally. An opening of 3in. diameter at bottom of basin with a short cylindrical neck allows escape of contents to soil pipe.

A valve of metal, moved by a pull or handle, working from outside basin, closes neck of basin to retain water, and opens to release it. The same pull causes flush from cistern above. A pipe called the overflow arm opens at upper end into basin in such position as to enable it to remain about two-thirds full of water.

This arm discharges into valve box and is bent to form a trap. It is an advantage if the overflow arm is open at top to allow access for cleaning; also that the flushing rim should be continued round to assist in cleansing the arm and to keep the trap always sealed.

The valve box of each pipe in which the valve works is between basin and a trap below, and is above floor.

A pipe opening at one end into valve box and at the other into outer air, affords ventilation, and prevents collection of foul gases that might escape into closet through valve opening when the basin is flushed.

A sheet lead safe (or shallow tray) is sometimes fixed on floor under closet to guard against possibility of drainage from overflowing of basin. A pipe conveys any water falling on the safe to the outer air. Passage of air inwards is prevented by a hinged flap.

The necessary amount of water to effectually flush a valve closet is not less than three gallons, and it is preferable that the flush be regulated by special mechanism known as a "supply valve and bellows regulator," rather than by the ordinary service box or waste preventer. The cistern to be supplied by ball valve, and to be at least 4ft. above pan, the discharge pipe 2in. diameter.

The trap beneath valve box (and under floor) should be preferably of lead, connected by a lead branch to a lead soil pipe with wiped joints, and properly ventilated to prevent syphonage.

Short hopper closets are of three kinds—the ordinary, shaped like a frustum of a cone; the "washout," which retains water in a depression in bottom of basin; and the "washdown." The latter only should be used; the others are not self-cleansing. The back of the "wash down" is nearly vertical, soil falling into water retained in throat of trap. A hollow "rim flush" effectually scours all parts of inner surface.

Service box is usually made to hold two gallons (three gallons would be better), and is emptied by a pipe not less than 1¼in. diameter, and 5ft. high from rim to cistern. On an upper floor lead trap and branch is best as for valve closet, but on the ground floor the stoneware trap in general use, connected direct with drain head, answers all necessary purposes.

NATIONAL HEALTH SOCIETY.

DR. A. T. SCHOFIELD has commenced a course of hygienic lectures to ladies in the Children's-room, Denning-road, Hampstead, under the auspices of this Society. At the first lecture there was a large attendance. The first part of the afternoon's lectures was devoted to explanatory matter concerning the skin covering of the body, illustrated by a diagram, and also dealt in facts and figures showing what is the true proportion of the bodily form. The lecturer showed that the true shape of the waist should be an oval and not a circle. He made a drawing on the blackboard of the shape of the foot, showing its beautiful arch, and said that too much standing alters this arch and causes its depression, whereas walking exercise is good and beneficial. After an interval, during which afternoon tea was served, the second lecture was given. It contained information of a practical character, such as methods of taking baths and thorough cleansing of the skin. Dr. Schofield said that before sponging the body with cold water it is safer to put the feet and legs in warm water, the effect of so doing being to withdraw the blood from the head and trunk, and so prevent all danger of congestion of brain or liver. He advised the use of salt water, and gave a practical hint as to how it might be made soft by adding to the ewer of water over night a little Maignen's Anti-Calcaire.

HASTINGS.—We are asked to state that samples of the water supplied to the Borough have just been submitted to the eminent analyst, Dr. Dupré, who reports that the waters are of great organic purity, and of the highest class.

THE MICROBE AS A PUBLIC BENEFACTOR.

In the course of a popular lecture on microbes at the London Institution, Mr. Bottomley reviewed for his hearers the history of the study of bacteriological science. It was in 1680 that Leuwenhoff first discovered by the aid of a simple form of microscope the microbes which exist on the teeth, but it was not until nearly 200 years later that the science was taken up in earnest—and we owe nearly all our present knowledge to the exertions primarily of Pasteur. The word microbe we owe to the Paris Academy of Sciences, who suggested it in 1878 as a ready compromise between the rival claims of the zoologists and the botanists for the possession of certain of the more minute growths; and Pasteur adopted and popularised the term. It now includes the fungoid growths—such, to take simple examples, as the fungus on jam, or the mould on boots, the "ferments," such as yeast, and the bacteria proper. A further sub-division of the micro-organisms divides them into those which look like billiard balls, these are the micro-cocci; those which look like lead pencils, these are the bacteria bacilli; and those which are spiral in form, the spirilla. But it is a mistake to regard all these micro-organisms as enemies of the human race. If it were not for microbes, where should we get the flavour in our tobacco from? Where the taste in our butter? Cheese of the Gorgonzola or the Gruyere or the old Stilton would be beyond our reach; and so would a "gamey" pheasant; and so indeed would be our best linen, which owes the process of "retting" to the action of a friendly microbe. But the best instance of the friendly microbe's services lies in that which is done by the phagocytes in our blood. These are micro-organisms belonging to the race, already mentioned, of billiard balls—the phagocytes exist as "diplo-cocci." Professor Mentschikoff, the Russian bacteriologist, has lately shown that inside the bodies—if such a term can be applied to micro-organisms so minute—of the phagocytes we may find the half-consumed bodies of unfriendly bacteria which the "phagocyte" has stalked and eaten. Another development of bacterial energy is witnessed in the case of the micro-organisms which appear upon the roots of plants. Everyone knows the old agricultural rule that you must not keep on "wheating" a piece of ground, but that wheat must succeed and be followed by a leguminous crop. The reason of this is that wheat wants more nitrogen than the leguminous plants for its growth; or, to express the same truth more accurately, the bacteria growing about its roots are of a different constitution from those of turnips or clover. Professor Hobbe, the German, has advanced this investigation a stage further. He has shown that certain plants, for their proper development and growth, must have certain microbes about their roots. He, therefore, makes cultivations of these mirobes in gelatine—and sells them at half-a-crown a test tube—so that the farmer can now water backward crops with a proper infusion of bacteria.

What the farmer more properly should do would be, however, to allow the requisite microbes to cultivate themselves among his seeds. The power of reproduction of these microbes is immense, and is due, of course, to the rapidity with which they bud and breed. A microbe, for instance, which doubles itself every half hour, as some of these can do, will have multiplied its numbers at the end of the day to 16,000,000. At the end of the second day, although you could easily get 250,000,000 of microbes on to a postage stamp, the microbes would so have multiplied that they would occupy a cubic pint, and at the end of the third day would weigh 8000 tons. Fortunately the struggle for existence among themselves, and the diseases which they develope forbid any such multiplication; and this consideration suggests the most fascinating branch of bacteriological study—the anti-toxins. For it is not the bacterial bacilli which kill, but their products which are inimical to the blood—just as the action of the fermenting microbe in yeast separates alcohol and sugar. And these products applied to an animal so as not to kill him produce in the blood other micro-organisms which are fatal to the first intruders. In this direction, perchance, the great future of medical science lies.

Sanitary Inspectors' Associations.

WESTERN BRANCH.

A meeting of this branch was held on Thursday, January 27th, at the Merchant Venturers' Technical College, Bristol, to hear an address by Dr. D. S. Davies, Medical Officer of Health, on the subject of "Some Methods of Investigation in Epidemic Diseases." Mr. W. J. Press, of Burnham, presided, and the hon. secretary, Mr. T. J. Moss Flower, read letters explaining the absence of the Mayor, the High Sheriff, and others.

Dr. Davies, who was well received, said the Sanitary Inspector was entrusted with the collection of the facts upon which the theory of causation was based, and upon the accurate collection of those facts the correctness of the theory, and therefore success in the prevention of disease, very much depended. Upon the knowledge of the natural history of disease depended the success of its prevention. One of the first steps towards an intelligent grasp of disease causation was a determination to rid one's self of any prevalent or popular idea such as that drains were the beginning, the middle, and the end of the causation of all infectious diseases. It was highly necessary to see that the drains of one's house were properly and scientifically constructed, but if Inspectors ran away with the idea that any disease, whether small-pox or scarlet fever, was wholly due to drains in one way or another, they would be hiding from view the possibility, and, in many cases, the certainty, that there were other causes at work spreading the disease. Dealing with the nature of infectious or communicable disease, he referred to the known existence of minute organisms which grew in or upon the tissues of the human body. The great majority of organisms performed useful functions, but a few flourished well at the temperature of the human body, and upon its tissues, and the ill-effects produced in the body were known as disease. Of course different organisms meant different diseases. By means of a blackboard Dr. Davies gave a table of diseases, and showed how they were usually communicated from one person to another, the

chief means of communication being the breathing of air containing the organisms. He explained the methods and means by which milk and other articles of diet became contaminated, and gave his hearers advice as to how they should set about to discover those methods and means. He impressed upon them the importance of systematic investigation instead of haphazard inquiries, and handed round specimens of the cards of instruction in use by the health department in Bristol.

YORKSHIRE BRANCH.

AT the annual general meeting of the Yorkshire branch of the Sanitary Inspectors' Association on Saturday, the 22nd ult. (Mr. T. Pridgin Teale, the president, in the chair), Mr. George Darley, superintendent of the Leeds scavenging department, read a paper on "The Destruction of Town's Refuse by Fire." Destructors, he remarked, had been in use in Leeds for twenty years. There were at the present time four, capable of consuming 80,000 tons of refuse per annum. When the first Leeds destructor (that at Beckett-street) was erected, the refuse was burnt by a natural chimney draught. Ten years later steam jets were added to the destructor, and these greatly increased the temperature. Similar jets had since been fitted to the other destructors in the city—at Armley, Kidacre-street, and Meanwood. The temperature obtained was from 1200 to 1500 deg. Fah. Mr. Darley affirmed that it would not be at all satisfactory to work a destructor without some means of obtaining the highest possible temperature either by steam jets or fans. He also added that the cost of dealing with a ton of refuse in Leeds was about 1s. 6d. A discussion followed, and, in reply to the president, Mr. Darley said the power for the forced draught in the destructor was got out of the refuse. Under the new system (Horsfall's) there was a comparatively small draught going up the chimney. Mr. Denham expressed the hope that small destructors, costing £30 or £40, would be made, so that in colliery villages the refuse from the pits might be got rid of. In reply to other questions, Mr. Darley said that about two-thirds of the refuse collected in Leeds was burnt. Tips were, of course, cheaper than a destructor for getting rid of refuse, but he condemned the use of tips. Dry ashes were largely used in Leeds on rhubarb fields.

CHINOSOL.

THE increased interest taken in the study of bacteria, and the identification of so many bacteria as the specific causes of disease, has brought the science of disinfection more and more into prominence. The number of so-called disinfectants or germicides has, in fact, grown to a bewildering extent, while the claims put forward would, if true, terrify all mischievous microbes out of their existence.

Probably the private purchaser buys what is most advertised without devoting any thought whatever as to the validity of such claims, but when large purchases are made for public bodies it often happens that the Medical Officer or the Analyst is asked to pronounce on the value of a given substance as regards its power of destroying dangerous bacteria.

To test the efficiency of a disinfectant it is necessary to bring it, in a given strength, into contact with infected matter, or with pure cultures of disease bacteria, and to ascertain whether after a stated time the disinfectant has succeeded in killing the bacteria.

Experiments of this nature are attended with considerable difficulty, and conclusions cannot at present be drawn with true scientific accuracy. Nevertheless, we can obtain what is for all practical purposes results that will enable us to say within moderate limits what strength will kill and what will not in a given time.

Besides germicidal power a disinfectant should have the power of destroying foul smells, and should, if possible, be non-poisonous.

All these properties are possessed in a marked degree by the substance we are considering, namely, chinosol. This body has a definite chemical formula, $C_9 H_6 N K S O_4$. It is a yellow chrystalline powder very soluble in water, and possessing a slight aromatic odour and an astringent taste.

Its germicidal properties are so surprising that they would hardly be credited were it not for the large amount of experimental work that has been done on it in America, Germany, and in this country.

It has recently been exhaustively tested by Mr. C. G. Moor (July, 1897), who examined its action on the bacteria of typhoid, diphtheria, anthrax, cholera, and on the chief organism of pus. His results show the germicidal power to be so great that even a tenth of an ounce in three gallons of water makes a reliable disinfecting solution.

Dr. Klein has (October, 1897) investigated the action of chinosol on bacillus subtilis, on anthrax spores, and on the staphylococcus pyogenes aureus.

The ability of a disinfectant to kill anthrax spores is a very strong proof of efficiency, and Dr. Klein states that a 1 per cent. solution of chinosol was fatal to them in five minutes, whereas they live for forty-eight hours in carbolic acid of five or six times the strength.

PLUMBERS, PLUMBING, AND PUBLIC HEALTH.

ON Friday, January 28th, Dr. MANSEL-HOWE, of London, delivered a lecture at the Town Hall, Maidstone, on "Plumbers, Plumbing, and Public Health." The Mayor of Maidstone presided, and there was a good attendance. The lecturer said much of the plumbing done to-day was not done by properly trained plumbers, with the result that much of the work was neither efficient nor reliable, and, unfortunately, exposed the inmates of many homes to disease which might and could be averted. Referring to the matter of sewer gas, he affirmed much sickness was traced to this finding its way into our dwellings, and stated that quite recently Professor Corfield and Dr. Payne had signified their belief in its powers of spreading typhoid. Dr. Robert Farquharson, M.P., had said:—"We all know that the modern system of drainage, if not carried out perfectly, is simply an elaborate machine for introducing disease into our homes." And Dr. Shirley Murphy had pointed out that the recent outbreak in Shoreditch was probably due to insuction of sewage matter into a defective water main. The lecturer advocated the soil pipe being

kept uniformly outside the house, and that both it and a separate relief pipe from the service drain should be carried to a point above the level of the highest portion of the house-roof, not too near to the chimneys.

He also contended that all inside waste-water pipes should constitute a system apart, and never communicate with the soil pipe or service drain, but made to discharge over an outside and properly-trapped gully. Similarly, all outside rain-water pipes should empty over outside gully traps, and never communicate with the soil pipe for the purpose of emptying their contents, and never with the object of serving as relief pipes. He further advocated efficient classes in connection with Technical Institutes for the better education and training of the rising generation of plumbers, and expressed the hope that Parliament would very shortly place the registration of plumbers under national recognition, so that when sanitary work had to be done, it might be undertaken by competent and responsible workmen. The lecture was illustrated with magic lantern slides, the subjects being for the most part examples taken from Dr. Vacher's work on plumbing defects.

Sir STUART KNILL, in moving a vote of thanks to the Mayor for presiding, stated that the Plumbers' Company were prepared to render any assistance in their power to the Authorities in improving the condition of sanitary plumbing.

The Rev H. COLLIS, Hon. Sec. to the Maidstone Technical School, thanked the Plumbers' Company for their assistance in connection with the establishment of classes for technical instruction for plumbing apprentices at the school.

THE SOCIAL AND SANITARY SOCIETY OF EDINBURGH.

THE work which has thus been carried on officially in Glasgow for twenty-five years has been done in Edinburgh since 1884 by voluntary visitors working under the auspices of the Social and Sanitary Society of Edinburgh. This Society divides the city into a convenient number of districts, appoints to each a superintendent—either a man or woman—and a staff of visitors. The duties of the visitors are practically the same as those of the women Inspectors in Glasgow, only their position is not official, and, their services being voluntary, their hours are not fixed, and they do not do so much work. On the other hand, there are more of them, the Society having on its books about two hundred visitors. These visitors consist principally of ladies recruited from the district visitors of the various parishes. They, therefore, have the advantage, or disadvantage as the case may be, of being personally known in the neighbourhood. They belong to all denominations.

The superintendents arrange for the visitation of each district, instruct the visitors to note insanitary conditions, and collect, tabulate, and forward to the Town Clerk the reports of the visitors. Cases requiring immediate attention are reported to the burgh Engineer or the Inspector of Cleaning and Lighting. Nine districts were visited in this way in Edinburgh last year.

The Society has done much valuable work. For eight years it directed its attention to the lighting of common stairs, keeping the matter before the Authorities by every means in its power, until at the present moment about 96 per cent. of the stairs are lighted and defaulters punished.

The inspection of dairies, byres, and milkshops has also been carefully considered by the Society's superintendents and visitors, and a scheme for further improvement in this direction is under consideration. The Society has been most active in suggesting and urging many reforms, some of which they have been mainly instrumental in carrying out. They have urged repeatedly the necessity of resident caretakers for common stairs, after the concierge system in foreign towns. They are still urging the necessity for various other improvements. Their most recent petition is that the Corporation should increase the number of Sanitary Inspectors, and that one or more of those appointed should be women.

The chief defect of the Social and Sanitary Association of Edinburgh is that it possesses no official status. Those who have worked in the poorer parts of great cities, in examining into the conditions of houses, factories, workshops, &c., know that it is far easier to get accurate information respecting existing conditions if the inquirers are armed with Government or municipal authority. The power of the law is a great lever in removing obstacles. It has been suggested that it might be possible by means of examinations to certify these visitors, and to register all those thus certified, supplying each with a card of registration signed by the Chief Sanitary Inspector of the city. The Sanitary Association of Scotland, which is the recognised examining body of Scotland, corresponding to the Sanitary Institute of England, only makes at present provision for examining in sanitary science with reference to sanitary inspectorships, but the board of directors is a strong and able one, and it is possible that were the need presented to them they might organise an examination in practical sanitary science (for persons who do not require the full Inspector's certificate), similar to that which is already held by the Sanitary Institute of England.

PUBLIC HEALTH PROGRESS IN THE QUEEN'S REIGN (1837—1897).*

By T. RIDLEY BAILEY, M.D., of Bilston.

REDUCTION IN THE GENERAL AND ZYMOTIC DEATH RATE.

Having now glanced at the progress made in certain departments of sanitary science during the Queen's reign, it is a natural step onward to examine the results as seen in the reduction of the general death-rate and the mortality from zymotic causes. A very instructive and interesting paper appeared in *Public Health* for June last, giving a comparison of the number and the causes of some of the deaths in England and Wales for the two periods 1838—42 and 1891—95, as found in the annual reports of the Registrar-General, from which most of the figures which follow are taken.

First, let me note that the population at the census of 1841 was very nearly 16 millions (15,927,867), and at the census of 1891, it had increased to just over 29 millions (29,002,525).

In the first quinquennium (1838—42) the mean

* Presidential address to the members of the Midland Branch of the Incorporated Society of Medical Officers of Health, October 7th, 1897.

mortality from all causes was 22,071 per million living, while in the last quinquennium it had fallen to 18,738 per million, or a decrease of 15·2 per cent. of the mean rate. In other words, instead of the 2,785,931 deaths registered in the last-named period there would, if the old rate had continued, and with the increased population, have been 3,280,850, or 495,459 more than the actual record, giving an average yearly saving of 99·091 lives.

The significance of this statement is even increased when we enter a little into detail and realise that more than half of this saving is due to the reductions from zymotic—which are preventable diseases.

The following are the averages of these diseases as given by the Registrar-General in his annual report for 1895:—

ENGLAND AND WALES.

	Rate per million living. Quinquennium.		Change in rate, per cent. of rate 1838—42.
Small-pox .. .. Chicken-pox ..	576	29	−95·0
Measles	539	408	−24·4
Scarlet fever .. Diphtheria	797	435	−45·6
Whooping-cough	504	398	−21·1
"Fever"	1053	185	−82·5
Diarrhœa .. .. Dysentery	254	630	+148−0
Cholera	44	21	−52·3

The greatest decrease is seen in the rate from small-pox, fever (typhus, enteric and simple continued), and cholera, and these have already been discussed.

The mortality from scarlet fever and diphtheria combined shows a deduction of 45·6 per cent., but the deaths from scarlet fever alone indicate a still greater reduction. In the decennial period 1851—61 the deaths from this disease were 88 per 100,000 of the population, and, notwithstanding fluctuations, there has been a steady, continuous diminution, until at present the average is only 17 or 18 per 100,000, or less than a quarter of what it was forty years ago. This reduction is due to several causes, (1) to the more thorough isolation of the sick and the destruction or disinfection of fomites; (2) to our increased knowledge of its etiology, whereby we are able to recognise the possibility of infection through milk—sometimes by direct contamination, *e.g.*, from persons in the dairy who suffer from the disease, or, as has been demonstrated by Power, Klein, and others, from a corresponding disease in cows ("Hendon cow disease"); and (3) to a more accurate means of diagnosis whereby cases formerly recorded as scarlet fever would now be recognised as diphtheria.

On the other hand, the increase in diphtheria has been very marked, not only in the number of cases but also in fatality. In the five years, 1859—63, the deaths from diphtheria were 95 per million, whereas in the similar period, 1891—95, they were 253. Various theories have been suggested in explanation of this very serious result, but time will not allow me even to mention them. It must suffice to state that our improved knowledge of its causation and methods of spread, while still obscure, justify us in the hope that it will soon be possible for us to bring it, as we are bringing the other infectious diseases, under the control of sanitation.

The following table, taken from the paper already mentioned, will show at a glance the saving of life resulting solely from the diminutions which have taken place in the mortalities from the zymotic diseases during the five years referred to, and will be far more eloquent than any words of mine :—

	Deaths in five years, 1891—95 Recorded.	"Old Time's" rate.	Gain or loss of lives. Five years.	Annually.
Small-pox Chicken-pox	3,515	85,622	+82,107	+16,421
Measles ..	60,584	80,122	+19,528	+3,905
Scarlet fever .. Diphtheria	64,846	119,471	+54,625	+10,925
Whooping-cough	59,142	74,920	+15,778	+3,155
"Fever"	27,546	156,528	+128,982	+25,796
Diarrhœa .. Dysentery ..	93,986	37,757	−56,229	−11245
Cholera	3,188	6,540	+3,352	+670

Mean population 1891—95, 29 732,504.

In this brief and most imperfect survey of public health progress during the past sixty years, no mention has been made of phthisis, puerperal fever, of diarrhœa, and of other diseases which require consideration, nor has anything been said of the evolution of sanitary laws and the extension of local government, of the improvement of our food supply and the more systematic examination of meat, fish, and other articles of diet; of the endeavours made to discover and prevent the spread of tuberculosis from the consumption of the flesh of infected animals; of the whole subject of bacteriological research and the development of the idea of inoculation for the prevention or modification of disease, and of the marvellous advances, too, in the hygiene of the Army and the Navy. Time will not allow of more than the bare enumeration of these matters, each of which might be made the subject of an extensive and interesting paper.

From the story of the past, however, we have every cause for congratulation and thankfulness. In the midst of great difficulties the men who were the pioneers of sanitary medicine raised it to a science, and from the history of their doings we may gather inspiration for further endeavour. It is the high privilege of sanitarians to be the leaders of the nation in social questions of the highest importance, and adequately to perform their duty they should be secure in the tenure of their office, receive a due appreciation of their position, a fair salary, and complete independence of local control. It is of the essence of their calling to teach statesmen and the other leaders of thought in the country the medico-physiological view of every matter, whether physical or moral, that affects the health of the people. It is our duty to say that every man should have the opportunity to earn a minimum living wage, and, conversely, that no man should be kept by the State who is strong and skilful enough to keep himself; that sweating in any trade and preventable accidents are detrimental not only to individuals but to the general interests of the community, and should not be allowed; that unhealthy trades should be further regulated by the State and their ill-effects counteracted; that the reform of our workhouses and prisons, and an improvement in their administration, is but a necessary obligation of our civilisation. Every locality, too, should be provided with suitable healthy dwellings for the artisan classes, let at such rents as the wages of the district will fairly cover, and where these do not exist the Sanitary Authority

should supply the need. Back-to-back houses should be absolutely prohibited. It is a check to pride in our sanitary progress that in Glasgow 20 per cent. of the population reside in single rooms, and that in the United Kingdom, according to the last census, over three million persons live in overcrowded tenements.

Recreation grounds or open spaces should be found in every town, and the mental over-pressure of children from the system of cram in education should be prevented by sounder psychological methods.

A proper system of sick nursing for the poor—that is for those not sufficiently destitute to be removed to the workhouse, and yet unable financially to provide for themselves—should be part of the regular equipment of every town and district. Whether this should be by the institution of State hospitals, or by the addition to the staff of every Sanitary Authority, or Board of Guardians, of one or more district outdoor nurses (in proportion to the number and needs of the population) who should be as much officers of the Authority as the Medical Officer of Health or the Poor Law Medical Officer, and whose services in all cases, infectious or otherwise, should be (under proper regulations, of course) at the disposal of all sick people, poor enough to be entitled to them, is a point for discussion.

These, gentlemen, are some of the things in which it is our duty to advise and to guide. In some of the most important matters that concern the well-being and the well-doing of every member of the community from his entrance into the world to his solemn exit, we have direct and serious responsibilities.

It should be our constant aim to favour and to create such a view of all matters that lie under our authority that every citizen, whatever his sphere of life, should grow up in such conditions—physical, mental, and moral—as will make the product—the whole man or woman—the best that could result from the initial germ. Too high a view cannot be taken of our positions as guides in sanitary medicine, and when we realise that the result to humanity of our labours is to prevent disease, to decrease, and where possible, to banish sickness and suffering, to diminish mortality, to prolong life, with all the consequent gain—in comfort, in freedom from pain, in true happiness, in usefulness of service, ay, and in measurable money value—I think we shall, one and all, be encouraged, more than ever, to renew our efforts and to labour on, each in his own sphere—

"In the unfailing hope, although
It be not granted us to see,
Yet that the coming age shall know
We have not wrought unmeaningly."

PRAISE FROM "THE LANCET."

THE TESTIMONY OF A GREAT MEDICAL JOURNAL TO THE MERITS OF MR. DIBDIN'S BOOK.

THE following review of Mr. Dibdin's "Purification of Sewage and Water" appeared in last week's issue of *The Lancet*:—

"Mr. Dibdin's work, in his recent capacity as chemist to the London County Council, is well known. He has had peculiar opportunities for studying great sanitary problems, and that he has not studied them in vain is evident from the work published from time to time in the official reports of the London County Council, and now practically summarised in the convenient form of the book before us. At once we may say that it is a most interesting work. It deals, for instance, with the recent developments in the treatment of sewage by bacteriological methods. Years ago we maintained in these columns that in principle the treatment of sewage with chemicals was illogical and wrong. Nature provides a method of purification, and, like all nature's operations, it is not a wasteful process. Chemical treatment, it is true, consolidated sewage and rendered it to some extent inoffensive, but that is all; nobody could use the product with any profit, and it was difficult to dispose of it satisfactorily. The study of the conditions under which the specific organisms work favourably has revealed, as Mr. Dibdin has shown, the possibility of employing these microscopic engineers to do the work not only of removing what is a source of offence and pollution but of converting it into a harmless, and, indeed, a valuable product. Instead of, for example, the solid matters of sewage being separated by chemical precipitation to serve no end and not improbably become a danger to the public health, it may be converted, by the silent but certain operations of specific micro-organisms, into nitrates, carbonic acid, and water, all of which are essential to plant life. Thus the great cyclic operations apparent in all nature's work are completed, whereas by chemical treatment they are impeded with, as might be anticipated, unsatisfactory result.

Mr. Dibdin has contributed, as the present work shows, not a little to the satisfactory solution of this vitally important problem. His instructive and interesting experiments with the sewage discharge at the great London sewage outfalls are convincing on this head. Mr. Dibdin's every-day duties as chemist to the London County Council also have brought him intimately into contact with the question of the purity of the London water supply, and his work in this direction has been repeatedly referred to in the columns of the *Lancet*. Notably, there is the inquiry he conducted under the auspices of the Council into the available sources of supply in Wales, and he certainly did good work when he caused considerable activity amongst the metropolitan water companies by his comparatively recent and unfavourable remarks upon the quality of metropolitan water, which were based chiefly upon more careful attention being paid to the kind and amount of suspended impurity. Mr. Dibdin has devised a micro-filter, which serves not only to estimate small quantities of suspended matter, but in isolating it to enable some idea of its nature to be gained. All these and kindred subjects are dealt with in the book. It need hardly be added that the book is sure to be held in estimation by all those interested in sanitary advance. It is an accurate and valuable gauge of the present position of matters relating to the more pressing questions of modern hygiene."

AN important meeting of Plumbers was held at Exeter on Saturday last, a report of which will appear in our next issue.

General News.

HOME.

NOTICE.—On and after 31st March next the Annual Subscription to this Journal will be raised to 12s. 6d. to all NEW Subscribers. NO ADVANCE will be made to our friends whose names are entered on our Subcription list prior to that date, so long as they continue to Subscribe.

YNISHIR.—Diphtheria is raging at Ynishir, and during last week two children succumbed to the disease.

RIPLEY.—The Local Government Board has sanctioned a loan of £2710 for water supply to the outlying wards.

BILSTON.—The Urban District Council has resolved to apply to the Local Government Board for power to borrow £6500 for waterworks purposes.

BOLTON.—A Local Government Board inquiry has been held respecting an application for sanction to borrow certain sums, including £10,255 for refuse disposal.

FARRINGDON.—A Local Government Board inquiry has been held into the scheme for the proposed water supply, and the loan of £4000 for carrying it out.

SOUTHAMPTON.—A Local Government Board inquiry has been held relative to an application by the Corporation to borrow the sum of £1080 for the purpose of erecting public conveniences.

PORTLAND.—The Local Government Board has sanctioned the application of the Portland District Council for power to borrow the sum of £35,000 for completing a scheme for supplying the island with water from Upwey.

HORNSEY.—The engineer is preparing plans and estimates for the erection of the new bath and discharge rooms at the isolation hospital, the Local Government Board having sanctioned the borrowing of the estimated amount of the cost.

NORTHWICH.—A Local Government Board inquiry has been held in response to an application by the Rural District Council for sanction to borrow £520 for works of water supply for the townships of Cuddington, Hartford, and Weaverham.

DOVER.—The International Sanitary Association have offered to construct two underground lavatories, one in the Market Square and one at the top of Biggin-street, near the Town Hall, and they propose to recoup themselves by charging a penny for the closets, twopence for the lavatory, allowing the stalls to be free.

DUNTOCHER AND DALMUIR.—A commencement has been made with the construction of a new reservoir for the Clydebank, Duntocher, and Dalmuir Water District at Greenside on the Kilpatrick Hills. A Provisional Order for this purpose was obtained by the County Council of Dumbarton last year, as owing to the rapid growth of Clydebank it was found absolutely necessary to augment the water supply. The work of construction will cover three years, and the cost will be between £30,000 and £40,000.

HARTLEPOOL.—The Gas and Water Company is promoting a Bill in Parliament for extending the waterworks.

HYTHE.—A Committee has been appointed by the Town Council with a view to finding means to increase the water supply.

BRIGHOUSE.—The Joint Hospital Board has decided to ask for the sanction of the Local Government Board to borrow the sum of £3700, making a total of £11,000 spent on the hospital premises.

BARRY.—A Local Government Board inquiry has been held into applications for power to obtain several loans, including £7950 for new works of water supply, including new mains, £1750 for new pumping engine, and addition to the existing building.

HEYWOOD.—Dr. Wisken, the Medical Officer of Health for Heywood, has decided that the day-schools of the town must remain closed for another week owing to the prevalence of measles. This will be the fourth week that they have been compulsorily closed.

NEWBURGH.—Mr. G. B. Macdonald has got his material forward at the school for carrying out the drainage portion of the new sanitary arrangements. The plans provide for an entirely new system of lavatories, closets, &c., costing about £350. But the advantages over the present very inadequate dry system in a school of nearly four hundred pupils are too obvious to require to be mentioned. The work will occupy about three months.

SELBY.—A County Council inquiry has been held into the subject matter of a report by the County Medical Officer to the effect that an isolation hospital or hospitals ought to be established for the use of the inhabitants of the Selby urban district, and for the rural district of Selby. The chairman said that the committee was satisfied that there was necessity for an infectious hospital in the district, and would make a report to the County Council.

BIRMINGHAM.—The Health Committee of the City Council recently discussed at some length the subject of the cleansing of courts, the shocking state of some of these places having been prominently brought under public attention at the Coroner's Court. The Committee has now decided to recommend the Council to authorise it to exercise oversight in the matter, and to cleanse the courts where desirable, charging the cost to the occupiers of the premises. We understand that the Committee contemplate the employment of twelve scavengers and a foreman for this purpose, the cost involved being estimated at £1000 a year.

GOOLE.—Proposals for purifying the Goole water were discussed at a recent meeting of the Gas and Water Committee. It was felt that a temporary expedient must be adopted at once. Even if the committee eventually decided to go to Heck, at least three years would elapse before this could be accomplished. Two alternative proposals were before the committee, one being to purify the water from the new bore by the Pulsometer system, and the other to utilise the pure water from the bore at Rawcliffe Bridge, and to soften, by the Mather and Platt process, sufficient water from the old well. The further consideration of the matter has been adjourned.

CORNWALL.—The Sanitary Committee of the County Council reports that the cases notified during December under the Infectious Diseases Act amounted to 205 against 85 in November. This is due to the typhoid fever epidemic at Camborne, the cause of which is at present being investigated by the Local Government Board Inspector.

SCOTLAND.—The Local Government Board for Scotland has issued draft regulations for regulating the duties of Medical Officers of Health and Sanitary Inspectors under the new Public Health Act. The Board understands the Act to imply that the initiative shall be taken by the Local Authority, and these regulations are put forward only for guidance and as suggestions. The draft indicates clearly what the Board may be expected to approve, and their approval is necessary under the Act.

Personal.

MR. T. G. DICKSON has been apppointed Medical Officer for the Radnorshire District of Hay.

MR. J. M. BENNETT has been appointed Medical Officer for the Ruddington District of Basford.

MR. J. BUCHANAN has been appointed Medical Officer of the Watford district of Watford Union.

MR. J. G. MILNES has been appointed Medical Officer for the Gislingham District of Hartismere.

MR. RICHARD JONES, M.D., has been appointed Medical Officer for the District Council of Festiniog.

MR. F. A. HALLAWORTH has been appointed Medical Officer for the Bodenham District of Leominster.

MR. G. HUDSON has been appointed Medical Officer of the Mildenhall Workhouse, and of the Worlington district.

MR. J. T. HALLAM has been appointed Assistant Surveyor for the urban district of Fenton, at a salary of £100 per annum.

DR. A. H. SMITH, of Yarm, has been appointed Medical Officer and Vaccination Officer for the Yarm district of Stokesley.

THE Town Council of Nelson has increased the salary of Mr. C. T. Copley, Assistant Borough Surveyor, by £25 per annum.

DR. NIELD COOK, D.P.H., Health Officer of Madras, has been appointed Health Officer of Calcutta, in room of Dr. Simpson.

MR. F. W. MAGER, Sanitary Inspector to the Dorchester Rural District Council, has been appointed surveyor for the Rural District of Walsall.

MR. J. W. HARRISON, A.S.I., Assistant Sanitary Inspector for Bradford, has been appointed additional Building Inspector for the borough of Birkenhead.

DR. ANNINGSON has been appointed Medical Officer of Health for the district of Royston, and Mr. H. N. Woodward, Sanitary Inspector, at salaries of £20 per annum.

MR. PHILIP E. PILDITCH has been appointed as one of the surveyors and umpires to the Board of Trade.

G. HOPE, L.R.C.P., M.R.C.S., has been appointed Medical Officer for the Seventh Sanitary District of the Brentford Union.

C. C. BRODRICK, L.R.C.P., L R.C.S., has been reappointed Medical Officer of Health for the Rural District of Tavistock.

M. M. HAILEY, L.R.C.P., L.R.C.S., has been reappointed Medical Officer of Health for the Urban District of Newport Pagnell.

H. T. EVANS, M.R.C.S., D.P.H,, has been appointed Medical Officer of Health for the Bedwellty Urban Sanitary District, vice J. T. James resigned.

Sewerage Schemes.

[TO MUNICIPAL ENGINEERS AND SURVEYORS.—The Editor will be pleased to receive items for publication relating to sewerage schemes projected or inaugurated, together with explanatory diagrams or photographs. The former should be drawn and lettered in black ink.]

THE Middleton Corporation has been granted six months' extension of time for the completion of the sewerage works.

A LOCAL Government Board inquiry has been held at Epsom with reference to the compulsory purchase of land for the Ashtead drainage scheme.

THE Corporation of Glasgow is promoting a Bill to confer upon it powers to acquire additional lands, and to construct additional works for sewage disposal purposes.

IT appears that a writ has been issued against the Dunstable Corporation owing to the alleged discharge of sewage matter and surface water from the Corporation's drains.

A LOCAL Government Board inquiry has been held at Warminster into the new sewage scheme for the town, to carry out which the Urban District Council had made application for sanction to borrow £5000.

A LOCAL Government Board inquiry has been held into an application of the Evesham Rural District Council for sanction to borrow £2000 for sewage works at Badsey. The Parish Council of Badsey opposed, chiefly on account of cost.

MR. SANTO CRIMP, of Messrs. Taylor, Sons, and Santo Crimp, has been conferring with the Dunstable Council on the proposed sewerage to be carried out for the borough, and it has been proposed to unite Houghton Regis in the sanitary area. Mr. W. H. Leete, the County Surveyor, has submitted a scheme on the broad irrigation of the intermittent downward filtration principle. The estimated cost is £6000.

A LOCAL Government Board inquiry has been held at Market Harborough into the application of the District Council for sanction to borrow £3550 for purposes of sewerage and sewage disposal for the parishes of Kibworth, Beauchamp, and Kibworth Harcourt.

A DEPUTATION of gentlemen from Hamburg visited the Barnhurst Sewage Works of the Wolverhampton Corporation on January 27th, for the purpose of inspecting their construction. Last year Russia sent representatives to Wolverhampton to inspect the sewage works.

THE Committee appointed to inquire into the cause of the pollution of the river Brent reports that the pollution has been traced to the sewage farm of the Hanwell Urban District Council, and the solicitor has been instructed to serve the Council with notice to abate the nuisance.

AT a recent meeting of the Penybont Joint Sewerage Board it was decided to adopt the sea outfall scheme submitted by Mr. Cousins, of London, with the supplementary scheme for carrying the outfall channel below low-water mark 1400 yards. The total estimated cost was £19,462.

A LOCAL Government Board inquiry has been held at Enderby into the application of the Blaley Rural District Council to issue a Provisional Order to empower the Council to obtain land required for works of sewerage and sewage disposal for Enderby, and for sanction to borrow £5000 for the purpose.

THE Urban District Council of Bexhill-on-Sea has just approved a complete sewerage scheme for Little Common, within the district, and has given instructions for the necessary plans and estimates to be prepared and sent to the Local Government Board with a view to an inquiry. The estimated cost is £4000.

THE bacteriologicsl system of sewage disposal is being adopted at Farnborough. Considerable interest is evinced in a scheme for extending the sewerage of the district, which is being prepared by the Surveyor at the request of the Council. A house-to-house sanitary inspection of the district is being made, and there appears to be a general desire for rapid sanitary progress.

Lighting.

THE Corporation of Gravesend is applying for an Electric Lighting Provisional Order.

IT is proposed by the Electric Lighting Committee of Islington Vestry to extend the electric lighting mains to Highbury. The adoption of the suggestion would confer a great boon upon the tradespeople of the neighbourhood.

THE Corporatlon of Brechin is applying for an Electric Lighting Provisional Order.

A COMMISSION has been given to Mr. William Arnot, lately electrical engineer to the Govan Corporation, to report on the subject of electric lighting.

THE Urban District Council of Aldershot has applied for a Provisional Electric Lighting Order under the provisions of the Electric Lighting Acts, 1882 to 1890.

THE Local Government Board has sanctioned the application of the Chesterfield Gas and Water Board for a loan of £15,000 for the partial fitting up of the new retort house.

THE Chelmsford Rural District Council has applied for a Provisional Order for the electric lighting of the parishes of Writtle, Great Baddow, Broomfield, Springfield, and Widford.

THE Town Council of Glossop has appointed a sub-committee to interview the manager of the Municipal Electric Supply Company, who are offering to furnish the borough with an electric light installation.

THE Chester Corporation has adopted a resolution of the Lighting Committee recommending that a feeder be laid to increase the pressure in the electric lighting mains in Brook and Foregate-streets, at a cost of £2050.

THE Wallasey Council has received the sanction of the Local Government Board to the borrowing of £8000 for gasworks purposes, and has also received the draft provisional order for power to borrow £40,000 for gasworks purposes, which were the subject of the inquiry held in November last.

THE Melton Mowbray Electric Light Company, Limited, are applying for an Electric Lighting Provisional Order in respect of the urban district of Melton Mowbray, and the parishes of Sysonby, Welby, Eye, Kettleby, Burton Lazars, and Thorpe Arnold in the rural district of Melton Mowbray.

THE scheme of electric lighting for the principal streets of Sunderland has recently been brought into operation. The illumination is obtained from large arc lamps placed at frequent intervals along the main thoroughfares, and the new lights improve the appearance of the town at night very much.

THE Ilford Urban District Council has adopted the report of the Electric Lighting Committee which recommended the Council to approach the Great Eastern Railway Company with a view to purchasing a piece of land adjoining Sylvan-road, Ley-street, as a site for the electric lighting station.

THE distinction of being the first village in the kingdom to be lighted by electricity is now claimed for Clapham, in the neighbourhood of which the High Sheriff of Yorkshire, Mr. J. A. Farrer, resides. Owing to the generosity of Mr. Farrer, it appears that for nearly two years the streets of Clapham have been lighted by electricity, a nominal charge of half-a-crown per annum being levied on each house.

AT a recent meeting of the Royal Scottish Society of Arts at Edinburgh, Mr. D. Bruce Peebles showed and described a simple generator for the production of acetylene gas. The machine, he said, was of an automatic type, and he fancied no one would have the slightest difficulty in making gas with it. A tank and gasholder were common to this class of machine, and it was only in details that improvements could be made. What he claimed was that he had made a very simple apparatus for opening the water supply as needed, and by which a number of generators or retorts could be used with a small gasholder. Following the description, a photograph was taken to demonstrate the actinic power of the light provided by acetylene gas.

THE Gas Committee of the Hull City Corporation met on the 25th ult., when the negotiations for the purchase of the Kingston Gasworks by the Corporation for the sum of £92,500 were practically complete. An offer was received from the Sutton, Southcoates, and Drypool Gas Company to supply the Corporation with all the gas it required for the area of the Kingston Gas Company at 1s. 6d. per 1000 cubic feet. The charge of the latter company is 3s., and it was arranged that the consumers should under the altered circumstances be supplied at 2s. 8d. per 1000, the balance between 1s. 6d. and 2s. 8d. to be applied towards the reduction of the increased burden caused by the purchase of the works. When that is discharged, then the price of gas will be further reduced to consumers, and the balance remaining applied to the relief of the general rates.

FOR some months past the question of lighting the Victoria Embankment and Westminster and Waterloo Bridges with electric light has been under the consideration of the Highways Committee of the London County Council. It is now proposed that 144 arc lamps shall be provided. The lamps on each side of the carriage-way of the Embankment will be 240ft. from each other, those on the parapet wall about 66ft. apart, whilst those on Westminster Bridge and in the Northumberland Avenue approach will be placed at convenient distances. It is proposed that the whole of the parapet lamps and the alternate lamps on each kerb of the Embankment, and also some of the lamps on Westminster Bridge, should be extinguished at midnight, thus decreasing to an appreciable extent the cost of maintenance. The capital expenditure for the installation will probably be about £25,300, of which over £20,000 would be for the building and equipment of the generating station and the laying of the mains. The probable annual cost of maintenance is stated at £3509.

Law Cases.

ALLEGED SMOKE NUISANCE.

(MILLARD *v.* WASTALL.)

THIS was an appeal in the Court of Queen's Bench, by case stated, from the decision of justices, dismissing an information under the Public Health Act, 1875, Section 91 and the following sections, charging the respondent with committing a nuisance by permitting black smoke to be discharged from a chimney not being a chimney belonging to a dwelling-house. A preliminary objection was taken to the information that the notice on which it was founded did not set out the works required to be done to remedy the nuisance. The objection was allowed, and the information was dismissed. Section 94 provides that the notice shall be a notice requiring the person causing the nuisance "to abate the same within a time to be specified in the notice, and to execute such works and do such things as may be necessary for that purpose."

Mr. F. LOW, for the appellant, contended that it was not in all cases necessary to specify in the notice works to be done in order to abate the nuisance, because in many cases, as in the present, no works were necessary.

The respondent was not represented.

Mr. JUSTICE DAY, in allowing the appeal, said that it was not necessary for the Local Authority to invent works to be done by persons whom they required to abate a nuisance. All that was required in the present instance was that the respondent should refrain from using such coal as caused the emission of black smoke from his chimney.

Mr. JUSTICE LAWRENCE said that it was no more necessary to prescribe works to be done to abate a nuisance of black smoke than it was to abate a nuisance caused by keeping a pig.

NEGLECTING TO REMOVE REFUSE.

MR. HENRY MANDY SIMMONS, of St. Leonards Villa, Seaside-road, Eastbourne, was summoned by the Corporation of Eastbourne, who sued defendant under Section 49 of the Public Health Act to recover £4 0s. 6d. for expenses incurred in removing an accumulation of filth.

The TOWN CLERK (Mr. H. W. Fovargue) prosecuted, and Mr. F. LAWSON LEWIS defended.

Evidence was given by Mr. Mitchener (Sanitary Inspector for the East Ward) and Dr. W. G. Willoughby (Medical Officer of Health).

An accumulation of manure near defendant's slaughter-house at Lower Drove was considered a nuisance by Dr. Willoughby and was removed by the Corporation, who sold it (110 loads to Mr. Duly of Roseland's at 1s. a load (£5 10s.). The cost of removal was £9 10s. 6d., and the Corporation therefore sued for £4 0s. 6d.

Mr. Simmons was called as a witness. He said the stable manure was not in any part of the yard attached to the slaughter-house. It was in the field next to the slaughter-house field.

Mr. LAWSON LEWIS: Under any circumstances would it be reasonable to sell manure at 1s. a load when it costs you 1s. 6d. to deliver it?

Mr. Simmons: I should say not. We were

selling at the time at 5s. a load delivered at the New College to Mr. R. F. Winch, the master who has just left.

By the Town Clerk: I sold manure to Mr. Whatmore at 1s. 6d. on the spot.

Mr. G. Whatmore, of 19, Commercial-road, said he agreed to buy the manure, and on going to remove it he found that the Corporation were taking it away.

The Bench ordered payment of £3 2s.

The CHAIRMAN said they did think the action of the Corporation had been rather summary. It was a little unreasonable, remembering that the heap had been there for a long time, and was the growth of months to go on a given day, and say "if you don't instantly remove it we shall have to put in force the provision of this statute."

DRAINAGE DISPUTE.

A NOVEL legal point has arisen in the case of Andrews *v.* the St. Olave's District Board of Works, which came before his Honour Judge ADDISON, Q.C., at Southwark County Court.

The action was a claim by the plaintiff, William Joseph Dawes Andrews, a solicitor, and the owner of houses in Vine-street, Tooley-street, to recover the sum of £24 9s. 2d. from the defendants, the St. Olave's District Board of Works, for work done.

Dr. BALL argued the case for the plaintiff, and Mr. MACMORRAN, Q.C., for the defendants, the facts not being in dispute.

It appeared that the plaintiff had served upon him in April last notices to remedy defects in the drainage of two of his houses. Plaintiff's surveyor had the ground opened up, and then discovered that the drainage of the two houses was combined.

Mr. MACMORRAN pointed out that in law, though quite contrary to common sense, if a man combined the drains of two houses in London surreptitiously and without the sanction and approval of the Sanitary Authority, then such drains became a sewer, and was repairable by the parish, but if he were ordered to combine them by the Local Authority then they remained drains, which had to be kept in order by the owner.

On finding that these drains were combined, the Surveyor paid a visit to the Record-office of the London County Council to ascertain whether an order has been made by the Sanitary Authority which existed at the time the drainage was laid down, and which would make them private drains. Finding, as he then thought, that such an order had been made, plaintiff carried out the work. When it was completed, however, the Surveyor discovered that he had made a mistake, and that no such order as he supposed existed had been made, consequently the drains were a sewer and repairable by the defendants. Thereupon the plaintiff brought this action to recover from the Local Authority the money he had expended upon executing the work, namely, £24 9s. 2d.

His HONOUR, in giving judgment, said he could find no ground in law upon which plaintiff was entitled to succeed and recover the money he paid. There would be judgment for the defendants, with costs.

(*To the Editor of* THE SANITARY RECORD.)

THE INFECTIOUS DISEASES NOTIFICATION ACT, 1889.

HOW IT WORKS IN RURAL DISTRICTS.

SIR,—As a matter of public interest I have thought it a duty to call attention to what I consider, and what I have proved to be in my official capacity of Sanitary Inspector, defects (serious defects) in the Act above referred to.

My remarks apply to the working of the Act in large rural districts, and I may here mention that my district is a large one, having an area of 32,000 acres and about 100 miles of highways. The Act was adopted by my Council, then the Rural Sanitary Authority, previous to my appointment in March, 1890; I have therefore had nearly eight years practical experience of the working of the said Act.

The particular section to which I desire to call the attention of my fellow-sanitarians who are entrusted with carrying out the conditions laid down in the Act is Section 3 (*b*), wherein it reads:—"Every medical practitioner attending, or called in to visit, the patient shall forthwith, on becoming aware that the patient is suffering from an infectious disease to which the Act applies, send to the Medical Officer of Health for the district a certificate," &c.

My object in writing you is with a view of ventilating this question of notification of infectious diseases and getting an expression of opinion and experience of others on the working of the Act in large rural districts.

The weakest point in the Act and Section mentioned, in my opinion, is, "shall forthwith notify to the Medical Officer of Health," this, I contend, is wrong, and the words "Medical Officer of Health" should read "the Sanitary Inspector," where the Act is adopted in rural districts, for the following reasons:—

In a large rural district, the principal population being agricultural and other labourers, the earnings of these men are very small compared with the town mechanic; consequently, when a member of the family becomes ill, they naturally defer calling in the family doctor as long as they possibly can, and the disease is therefore, in the majority of cases, in an advanced stage, and the doctor can therefore at once form a true diagnosis of the disease from which his patient is suffering.

We will now assume the patient to be suffering from scarlet fever, and there are eight or nine in family (in a six-roomed cottage—the maximum size in rural districts), and the family doctor having a large practice, and the house one, or, say, five miles from his surgery. We may at once take it for granted that the certificate under the Act referred to will not be forwarded to the Medical Officer of Health until the last post at night (and even this is more than we can reasonably expect from a busy medical practitioner). The Medical Officer of Health receives it in due course; he then in turn forwards the same on by post to the Sanitary Inspector, who may be, and most probably, if

he be a worker, will be from home, miles in the country, and when coming home late in the day tired, he is not fit or equal to undertaking another journey to investigate the case of which he has received notification from the Medical Officer of Health.

All this correspondence you will readily see must occupy from three to four days, and during this time several other members of the family may have contracted the disease, and, to say nothing of the suffering, some cases may, and have, proved fatal. When all of this could have been prevented, in districts like my own, where we have an isolation hospital, were only the Act made to read "Sanitary Inspector" in the section referred to instead of "Medical Officer of Health."

And still another difficulty frequently occurs; after all the delay of three or four days, as described above, the Inspector visits the house to find the doctor has left instructions for him (the Inspector) to the effect that he must on no account remove his patient, or he may die on the way. Thus the house, small as it is, badly lighted, insufficiently ventilated, and to some extent overcrowded, has to be left a centre of infection probably in a large village, when all this suffering and spreading of the disease might have been prevented.

I may, therefore, say in conclusion, if the notification Act is ever to be in the rural districts, what it was no doubt intended to be, for the prevention of the spreading of infectious diseases — in my opinion, derived from eight years experience with the Act, the medical practitioner visiting patients in the rural districts must send their certificates direct to the Sanitary Inspector.—Yours faithfully,

H. T. SIDWELL, C.E., F.I.S.E., A.S.I,
Surveyor and Sanitary Inspector to the Blean Rural District Council.
Herne, near Canterbury, January 26th.

THE VACCINE MARKS THEORY.

SIR,—The question of vaccine marks has been raised in your excellent SANITARY RECORD in the interesting article by Dr. T. Ridley Bailey which appeared in your issue of January 14th. I should like to be permitted to offer a few observations. The *Lancet* says:—"Among the best ascertained points in the matter of vaccination is the fact that the protection is in proportion to the number and size of the vesicles produced, which leave pitted cicatrices." Permit me to say that this authoritative dictum, so unhesitatingly pronounced, is by no means generally accepted by the profession. The medical vaccination census (Dr. Makuna's "Transactions of the Vaccination Inquiry") was taken with a view of settling the "vexed" question of vaccination from the medical side for ever, and particularly to turn back the tide of revolt against vaccination law.

The circular drawn up by the Exeter Hall Committee contains seven questions, and was sent to 4000 medical practitioners, including all the Public Vaccinators, Medical Officers of Health, &c. Of these questions, No. 4 refers to the quality and quantity of vaccination as determined by the cicatrices. An analysis shows that 27 medical men consider one cicatrix sufficient for all purposes; 25 require two; 54 recommend three; 92 prefer four; 10 insist on five; 5 desire six; whilst 28 declare that protection against small-pox is in proportion to the number of cicatrices, the more the better. Dr. A. W. Jacob, F.R.C.S.I., Dublin, avers that:—"Cicatrix supplies doubtful evidence of protection." Dr. M. S. Bernard Roth, F.R.C.S.:—"One well-marked cicatrix is as good as half-a-dozen." Dr. James Matthews "has several times proved that one good cicatrix is as good as a dozen." Dr. G. F. Henry, L.R.C.P., Bury St. Edmunds, declares:—"One is as efficacious as fifty." Dr. D. H. Cullimore, London, "has seen some of the worst cases of small-pox amongst the re-vaccinated Sepoys with many marks, and some of the mildest amongst the non-vaccinated Indians." Dr. C. H. Hill, London, says:—"The worst case I ever saw of post-vaccinal small-pox presented the very model of a vaccinated arm." Dr. C. Holmes deprecates many cicatrices, from which he has "seen serious local mischief," and so on throughout, one condemning *in toto* what another brother practitioner finds in every way desirable. The result of this medical vaccination census has been to establish, according to the vaccinatists:—First, absolute certainty (on the evidence of two-thirds of the entire body of medical experts) as to the danger of imparting serious and fatal diseases by the operation. Secondly, the greatest uncertainty as to the protection (if any) afforded. Thirdly, utter contradiction and confusion as to the mode of the operation, the kind of lymph required, the number of punctures necessary, and the advantages to be derived from the compulsory enforcement of the practice.

Such are the *dicta* of medical science concerning a prescription which has been vaunted as the greatest and most beneficent discovery in the history of medicine. Yet this prescription is so frequently attended with mischievous and sometimes fatal results, that thousands of intelligent Englishmen refuse to accept it without the aid of the policeman, and prefer to undergo the seizure of their household goods and the prison cell. It is to be hoped that when Parliament meets consideration will be given to the unanimous recommendations of the Royal Commission as disclosed in the final report, and that the result of the deliberations may be the total disestablishment and disendowment of this cruel and mischievous system.—Yours faithfully, JAS. R. WILLIAMSON.

Notes and Queries.

[Subscribers have the privilege of obtaining advice in this column on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed to THE EDITOR, "Notes and Queries," THE SANITARY RECORD, 5, Fetter-lane, London, E.C.]

NOTE.—If an answer be required immediately, a stamped addressed envelope must be enclosed, when we will endeavour to furnish a copy of the answer by post, as owing to the large number of queries received we cannot guarantee the insertion of a reply in the succeeding issue.

951.—BACTERIA TANKS: MODE OF CONSTRUCTION.—"A. K. B." writes:—"I am building a house in the country, and am anxious to deal with the sewage therefrom on the bacteriological method. I propose to catch the solids and bury them, and purify the liquid by filters. There is a good fall on the land; and if the effluent can be made pure enough, I should like to pass it into some pools, so as to keep the water level up in summer. I prefer filters before the septic tank, as I fancy there are possibilities of sewer gas being generated extensively about the septic tank. I have read Mr. Dibdin's articles with great interest, but am troubled with the following difficulties:—(1) The bacteria will not work during frost. Must the filter, then, be built under cover, and perhaps warmed in winter? (2) How is the filter to be built so as to secure constant aëration? (3) Is the breeze to be put into the solid tank, with air-pipes running into it, starting above the top level? (4) If it is to be open all round, how is the sewage to be confined in it? (5) Is the rest the filter will get every night enough, or had I better have filters for alternate use?"

Answer.—We advise our correspondent to procure Dibdin's "Purification of Sewage and Water," price 21s., and Spinks' "House Drainage Manual," price 5s., both of which contain valuable chapters on the bacteria tank at Sutton, and which give full particulars of the mode of construction of bacteriological filters, the latter named book containing illustrations, which will be most useful to him. It will not be necessary to intercept the solids, except so far as they are retained by the screens, which are provided mainly to intercept paper. The solids may be dug into land in the same manner as applying ordinary manure. The effluent should be pure enough to discharge into pools, and if the filters are properly managed the effluent will not undergo putrefaction. It is incorrect to state that the filters will not work during frost. We understand that the Sutton filters are not affected by frost. The filter should not be covered, and warming is unnecessary and unpractical. It may be constructed with walls and floors of concrete or masonry, or, where the ground is stiff clay, the filters may be constructed without artificial walls. The aëration of the filters is secured by the alternate filling and emptying of the filter, and allowing it an interval of rest of two or more hours. We understand that the filters so successfully adopted at Sutton have not perforated walls. It is preferable to have the filters in duplicate.

952.—DRAIN OR SEWER: VESTING OF SAME.—"J. B." writes:—"Referring to your answer to Query No. 928 in your issue of January 14th, will not the passage shown in the sketch come under Sec. 150 of the Public Health Act, 1875, and the sewer be the property of the owners of the houses until such time as it is taken over by the Local Authority?"

Answer.—Unless a Local Authority, immediately after the completion of a new sewer in a private street, express by notice in writing to the owners their dissatisfaction with the construction of the sewer, they will be unable to divest themselves of the vesting of the sewer imposed by Sec. 13 of the Public Health Act, 1875, which prescribes that "All existing and future sewers within the district of a Local Authority, together with all buildings, works, materials, and things, belong thereto, &c., shall vest in and be under the control of such Local Authority." In a similar case Bonella *v.* Twickenham Local Board, 18 Q.B.D. 577; 56 L.T. (N.S.) 486, affirmed in Court of Appeal, 20 Q.B.D. 63; 52 J.P. 356, where a sewer had been laid in a street by private persons, and had vested in the Urban Authority, under Sec. 13 it was held that the Urban Authority could not require the owners to lay a new sewer when a new system of drainage had to be adopted. In Barrow-in-Furness (Mayor, &c., of) *v.* Dawson, decided on 4th December, 1890, Smith, J., held that it was a question of fact to be decided on the evidence whether an Urban Authority had expressed satisfaction with, or were, in fact, satisfied with the sewer as originally constructed; but he accepted the principle laid down in the Twickenham case that "if after the lapse of a reasonable time after the vesting of sewers in a Corporation, they had done nothing and expressed no view on the subject, it must be taken to be conclusive as a matter of fact that at the time the sewer was originally constructed they were satisfied with it for the purpose for which it was then used."

953.—PUBLIC HEALTH (SCOTLAND) ACT, 1897.—"A. B." writes:—"(1) Under this new Act policemen have to report nuisances. Where are they supplied with a copy of the Act or with the necessary instructions? (2) Where do Inspectors of Nuisances obtain copies of the Acts? Surely they are not expected to buy them?"

Answer.—(1) It is provided by Sec. 19 of the Act that it shall be the duty of every officer of a Local Authority, and of any constable or officer of police of the county or burgh, in accordance with the regulations of the Authority having control over him, to give information of any nuisance under the Act to the Local Authority, and it shall be the duty of the said Authority to make the said regulations. A constable of police will, therefore, act under the regulations furnished him by his Authority. It will not be necessary for him to be supplied with a copy of the Act. (2) Inspectors of Nuisances will obtain a copy of the Act at the cost of the Local Authority.

954.—REFUSE DESTRUCTORS: NUISANCES FROM.—"G. S." writes:—"(1) Would it be desirable to allow the erection of destructors for destroying the excreta and household refuse in close proximity to the public abattoirs or in the vicinity of dwellings? (2) Would such works be likely to create any nuisance, or be a menace to the health of those living close by? (3) Would it not be advisable to have all such works away from centres of population, and if so, why? (4) Can you give me any reference as to the effect of dust destructors on the Public Health?"

Answer.—(1) It is inadvisable to select a site for the erection of a refuse destructor adjacent to public abattoirs, and in closely populated districts, except when no other site is procurable. (2) There is no proof of refuse destructors creating nuisances injurious to health where such destructors have been properly designed and carried out. From some destructors there is, however, a nuisance from fine dust passing up the chimney shaft and being deposited in the immediate neighbourhood of the destructor, but the most serious objection is that caused by the carting of refuse in the streets converging to the refuse destructor. (3) For the reasons stated in (2) it is always to be preferred that destructors be erected away from populous districts if sites can be procured. (4) We are not aware that any statistics are procurable to show that destructors have been prejudicial to the health of the neighbourhood in which they are placed.

955.—WORK ORDERED BY SANITARY INSPECTOR ON PRIVATE PREMISES.—"Sanitas" writes:—"(1) Has an Inspector of Nuisances any power to order work to be carried out by a workman, employed by the landlord, without proper legal notice being first served by the

Sanitary Authority? If so, under what Act and section? (2) Would the landlord be within his legal right in refusing to pay for work which was not ordered to be carried out by him? (3) Could you tell me if there has been any similar case tried before a Court?"

Answer.—(1) An Inspector of Nuisances has not any statutory power to enforce, except after reporting to his Authority, the carrying out of sanitary works. The Local Authority are the judges of the sufficiency or otherwise, acting on the report of the Inspector of drainage and sanitary conveniences, &c., and generally it is necessary that the Sanitary Authority must serve a statutory notice on the person in default. We are inclined to the opinion that in this case the Sanitary Inspector pointed out to the workman what was necessary to be done, in which he was acting properly in the discharge of his duties, and no doubt in the best interests of the owner of the property. Such direction on the part of the Inspector would not involve him in any liability for payment. (2 and 3.) In a somewhat similar case, decided in the City of London Court (Clarke *v.* London, September 16th last), where a builder did certain work at premises in the City of London, belonging to the defendant, and where the order for the work in question was given by the Sanitary Inspector, the owner knowing nothing whatever of the matter, the learned judge made use of the following observations:—"If a Sanitary Inspector required work done, a builder was bound to do it. Under the Sanitary Acts a landlord was liable for such work, although he did not give any order." Mr. Gathercole, the Sanitary Inspector, said the work was done on his verbal order. The learned Judge gave judgment for the amount claimed, with costs. Although the above case was one under the Public Health (London) Act, 1891, and too much reliance must not be placed upon it, it may, however, be helpful to our correspondent.

956.—Parochial Charities: Publication of Accounts.—"L. W. M." writes:—"A charity (not belonging to a church) is now distributed by trustees, appointed according to a scheme formulated by Charity Commissioners. Should the accounts be brought before the Parish (Council) meeting according to the Act, or is it not necessary?"

Answer.—Sec. 14 (Sub-section 6) of the Local Government Act, 1894, requires that the accounts of all parochial charities (not being ecclesiastical charities) shall be laid annually before the Parish Meeting of any parish affected thereby, and the Charitable Trusts Amendment Act, 1855, shall apply as regards transmitting accounts, &c., annually to the Charity Commissioners, and a copy thereof is to be delivered within fourteen days to the chairman of the Parish Meeting, and the names of beneficiaries of dole charities shall be published annually in such form as the Parish Council (or where there is no Parish Council, the Parish Meeting) shall think fit. In the case mentioned by our correspondent the accounts should be required to be submitted in conformity with the Act. We may also point out that the Parish Council appear to have power to appoint additional members on the governing body of the parochial charity, if it does not already include persons elected by the ratepayers, and of such number as may be sanctioned by the Charity Commissioners.

957.—Steam Disinfector Discolouring Linen: Remedy.—"E. R." writes:—"Lately a Reck's disinfector has been fixed in our district. We are troubled with the discoloration of the articles disinfected, which on being removed have a dirty, spotted appearance, and no amount of washing will cleanse them. Can you suggest a remedy? I may say that everything in connection with the disinfector is made of iron, and that the water supply is of a very soft nature."

Answer.—The discoloration referred to is, doubtless, oxide of iron or rust, which is so readily formed when the interior of the chamber is alternately exposed to air and moisture. A very simple remedy is to apply a coating of freshly-slaked lime to the whole interior, having made it previously thoroughly dry. A wash of Portland cement will also be similarly found effective. Allow the coat to dry before the apparatus is again used. Renew the wash as occasion requires.

958.—History of Sanitary Administration.—"Clerk" writes:—"Can you refer me to any publication containing a history of sanitary administration, *i.e.*, dealing with the effects in particular localities of the carrying out of sanitary improvements upon population, the public health, the death-rate, &c.?"

Answer.—We are of opinion that our correspondent will find the Annual Reports of the Medical Officer of the Local Government Board of considerable assistance, and superior to any other publication for his purpose. In the ninth report of the Medical Officer of the Privy Council (fo. 866) will be found an excellent table of the effect of sanitary works on the general annual death-rate, and on the mortality from typhoid fever and phthisis in a large number of towns in the country. The reports are published by Messrs. Eyre and Spottiswoode.

Vacancies.

Clerk of Works (Teignmouth, February 9th).—For the Urban District Council. Mr. C. Jones, surveyor and engineer to the Council, Town Hall, Teignmouth.

Electrical Engineer (Barrow-in-Furness, February 8th).—For the Corporation. Commencing salary £200 per annum. Chairman of the Electric Lighting Committee, Town Hall, Barrow-in-Furness.

Engineer, &c. Bury (Lancs.), February 7th.—For the Gas Committee. Salary to commence at £350 per annum. Mr. John Haslam, town clerk, Corporation Offices, Bury.

Engineer and Surveyor (Derby, February 12th).—For the Corporation. Salary £600 per annum, increasing by £50 per annum to £750. Mr. H. F. Gadsby, town clerk, Town Hall, Derby.

Engineer's Assistant (London, S.E., February 12th).—For the Baths and Wash-houses Committee of the Vestry of St. Mary, Newington. Salary £2 per week. Application forms supplied by Mr. L. J. Dunham, clerk, Vestry Hall, Walworth-road, S.E.

Sewage Works Manager (Haslingden, February 7th). — For the Haslingden, Rawtenstall, and Bacup Outfall Sewerage Board. Mr. R. W. Bugler, clerk, West View, Haslingden.

Surveyor (London, E.C., February 7th).—For the Worshipful Company of Ironmongers. Clerk, Ironmongers' Hall, Fenchurch-street, E.C.

Water Inspector (Basingstoke, February 12th).—For the Council. Wages £1 10s. per week. Mr. George Fitton, borough surveyor and waterworks manager, Town Hall, Basingstoke.

Sanitary Inspector (London, S.E., February 15th).—For the Vestry of St. Mary, Newington, London. The salary will commence at £110 per annum, with an annual increment of £5 to a maximum of £150. Application forms supplied by Mr. L. J. Dunham, vestry clerk, Vestry Hall, Walworth, S.E.

Sanitary Inspector (London, S.E., February 8th).—For the Lewisham Board of Works. Salary, £100 per annum, with an annual increase of £10 to £150. Mr. Edw. Wright, clerk, Lewisham Town Hall, Catford, S.E.

Sanitary Inspectors (London, S.W., February 9th).—For the Vestry of St. Mary, Battersea. No. 1 District, salary £150 per annum; No. 2, £101; No. 3, £141; No. 4, £150; No. 5, £101; No. 6, £150; No. 7, £150; No. 8, £140. Mr. W. Marcus Wilkins, vestry clerk, Municipal Buildings, Lavender Hill, S.W.

Contracts Open.

The dates given below are the latest up to which tenders can be received.

DENTON (LANCS).—February 5th.—Sewerage Works.—Messrs. Lomax and Lomax, 11, Fold-street, Bolton.

HOUGHTON-LE-SPRING.—February 5th.—Removal of Refuse.—Mr. John Geo. Baty, clerk, District Council Offices, Houghton-le-Spring

LONDON, S.W.—February 9th.—Reconstruction of Drainage, &c.—Mr. T. W. Aldwincle, 1, Victoria-street, Westminster.

SWANSEA.—February 7th.—Sewer.—Mr. R. H. Wyrill, Guildhall, Swansea.

WOLSTANTON (STAFFS).—February 7th.—Scavenging.—Mr. Jas. Beech, Inspector, Brownhills, Tunstall.

ABERDEEN.—February 8th.—Sewer, &c.—Mr. William Dyack, Burgh Surveyor.

COTEHILL (CARLISLE).—February 8th.—Sewer Pipe.—Mr. W. Crosthwaite, Sanitary Inspector, Stanwix.

ROCHDALE.—February 8th.—Sewer Work.—Clover Croft Works, Hamer-lane, Rochdale.

BIRKENHEAD.—February 14th.—Removal of Night-soil, &c.—Chief Inspector of Nuisances, Town Hall, Hamilton-square.

CHEADLE (STAFFS).—February 16th.—Sewer, &c.—Mr. F. T. Inskip, Surveyor, Brook House, Cheadle.

TIPPERARY.—February 14th.—Sanitary Works.—Mr. Joseph Gubbins, clerk, Workhouse, Tipperary.

BURNLEY.—February 16th.—Mr. S. Edmondson, district surveyor, 18, Nicholas-street, Burnley.

ASTON MANOR (BIRMINGHAM).—February 17th.—Sewer.—Mr. H. Richardson, A.M.I.C.E., Engineer's Offices, Council House, Aston Manor.

COMPETITIONS.

WINCHESTER, February 28th.—Public Baths.—Full particulars, with plan of site, to be obtained on deposit of £1 1s. on application to the City Surveyor, Guildhall, Winchester, which will be returned on receipt of a *bonâ fide* set of plans. Premiums of £25 and £15 will be awarded for the designs adjudged by the Council of sufficient merit, and placed first and second in order respectively. Drawing and detailed estimate to be deposited at the office of Mr. Walter Bailey, town clerk, Guildhall, Winchester.

To Surveyors, Sanitary Inspectors, &c.—First-class Cycles at reasonable prices. Don't place your orders elsewhere until you have seen our post-free catalogue.—MELROSE CYCLE COMPANY, Coventry.

"The Purification of Sewage & Water."

By **W. J. DIBDIN**, F.I.C., F.C.S., &c., late Chemist to the London County Council.

PRICE 21s. Net.

(*With numerous Illustrations and Diagrams.*)

THE SANITARY PUBLISHING CO., LTD., have much pleasure in announcing the publication of a new and important work, entitled "THE PURIFICATION OF SEWAGE AND WATER," written by Mr. W. J. DIBDIN, F.I.C., F.C.S., &c., late Chemist to the London County Council.

The subject matter, in a modified form, has appeared in *The Sanitary Record*, and the articles aroused so much interest, that a demand at once arose for publication in book form, and it is in response to this demand that a first edition of 1000 copies has been prepared.

In view of the terrible typhoid epidemic at Maidstone, and the liability of the great centres of population to similar outbreaks, a work of this nature, which deals most exhaustively with the subject of sewage and water purification from the very latest scientific standpoint, cannot but be most opportune. There is not a Local Authority, in fact, that can afford to be without it, and the publishers venture to predict its speedy adoption as a standard work among public health authorities at home and abroad.

SYNOPSIS OF CONTENTS.

Introduction.—Chapter I. Foul Matters, their Character and Composition. Combustion and Oxidation. Putrefaction. Bacteria.—Chapter II. Antiseptics, or Preservation for Limited Periods. Bacteriological Methods.—Chapter III. Various Proposed Methods of Artificial Purification. Precipitation.—Chapter IV. Experiments at Massachusetts, London, and Sutton. —Chapter V. Nature's Method at Work. New Departure at Sutton, Surrey. The Septic Tank System at Exeter.—Chapter VI. Analytical Methods Suitable for Watching the Progress of the Purification of Sewage.—Chapter VII. Interpretation of the Results of Analyses.— Chapter VIII. The Absorption of Atmospheric Oxygen by Water.—Chapter IX. Suggestions for Sewage Works Conducted on Biological Principles.—Chapter X. The Purification of the Thames.—Chapter XI. Ventilation and Deodorisation of Sewers —Chapter XII. The Filtration of Potable Water.—Chapter XIII. The Character of the London Water Supply. Microscopical Character of the Suspended Matters. Bacteriological Examination. The Effect of Softening the Present Supply.

PRESS OPINIONS.

"The book is one that no engineer engaged on works of water supply and drainage can afford to omit from his library, and a book that with all its technical features would none the less afford valuable education to many county and district councillors."—*Western Morning News.*

"The experiences and researches of Mr. Dibdin in respect to the treatment of sewage are so widely known . . . . that the publication of the present work will be hailed with satisfaction, and should be followed by the most valuable practical results . . . . packed with facts and technical information . . . . would be of the utmost value if it contained no more than the full description of the process (and its results) now in use for purifying the water of the river Thames."—*Newcastle Daily Chronicle.*

"The author's long experience in dealing with problems relating to the disposal of sewage in London, in his capacity of chemist to the London County Council and to the late Metropolitan Board of Works, and the success which has met his efforts, fully justify the issue of this record of his experiences and observations. . . . The book is such a readable one, and the subject so interesting to all dwellers in this city, where not only our system of sewage disposal is at fault or insufficient, but even our atmosphere is polluted, that one is tempted to continue quoting from it. Our city fathers will do well to give it a careful perusal."—*Glasgow Herald.*

"The book will well repay careful perusal. Every health officer should possess it."—*British Medical Journal.*

"A most interesting and welcome contribution to our information upon a problem of world-wide importance. The volume in appearance and finish is calculated to do credit to the Sanitary Publishing Company . . . . is or a most readible character from beginning to end."—*The Chemical Trade Journal.*

"Pure sewers nnd pure water supplies are the objects aimed at in the publication of this valuable work. The author is well-known of an authority on the subject of which he writes, and has done splended work in connection with the purification of the Thames and the treatment of London sewage.—*Liverpool Daily Mercury.*

"The book is excellently got up, and will be read by all interested in sanitary questions. It is so clear and popular in style that the ordinary non-scientific reader can have no difficulty in following Mr. Dibdin's clear account of another application of bacteriology to the problems of life and health."—*Leeds Mercury.*

"A most interesting work . . . sure to be held in estimation by all those interested in sanitary science. It is an accurate and valuable gauge of the present position of matters relating to the more pressing questions of modern hygiene."—*The Lancet.*

SANITARY PUBLICATIONS.

☞ The following books, which are either published or sold by the Sanitary Publishing Company, Ltd., 5, Fetter Lane, London, E.C., will be forwarded to any part of the United Kingdom post free on receipt of published price. Books marked "net" will be forwarded at published price, plus postage.

SMALL-POX IN THE GERMAN ARMY AND AMONG THE FRENCH PRISONERS IN 1870–71.

By EDWARD F. WILLOUGHBY, M.D. (London).

To those who know anything of the perfection of the military organisation of Germany the statement that the mortality from small-pox had not been recorded, or the notion that the machinery had been dislocated by the war, would be, on the face of it, incredible, even when supported by the answer of Lord Granville in the House of Lords. But Lord Granville was in office from 1880 to 1885, and at that time he was correct in stating that the statistics in question had not been published. It was in 1886 that the medical history of the war appeared in seven stout quarto volumes, a colossal undertaking such as no other country could have produced. Besides a full description of the organisation of the service, construction of hospitals, methods of performing surgical operations, with analyses of results, dietaries, &c.; every case of illness or of wounds admitted to the hospitals in the field or at home from every separate batallion, or other unit of that vast host of over a million men, as well as from some 375,000 French prisoners, is recorded and tabulated under several heads, with full discussions of the etiology, pathology, complications, treatment, and, in a large proportion of the fatal cases, of the *post mortem* appearances; constituting the work an encyclopædia of military medicine and surgery. And yet Dr. Hadwen, Mr. Tebb, and the rest, twelve years after their publication, have the impudence to deny the existence of these reports, and to accuse those who, like myself, have seen and read them, of wilful deception!

However, to be scrupulously accurate, I will confess that I, writing from memory of what was common knowledge prior to the authoritative publication of the official reports, have in my books and contributions to the journals, under-estimated the number of deaths from small-pox in the German army in the field. They were not 263 as I have stated, but 278. The 23,469 deaths in the French army during the war I gave on the authority of Dr. Chenu, chief of the Medical Department of that army, who, of all men, ought to know. The *average strength* of the German armies actively engaged was 788,213, but if one add to this number the drafts continually joining to fill the places of the killed and wounded, and of those who died, or were invalided by disease, one million will be no excessive estimate of the total. Among these there were 4835 cases and 278 deaths.

The total number of French prisoners interned in Germany was 374 995, though, as they were brought in successive batches after the great battles during August, 1870, and the surrenders at Strassburg, Sedan, and Metz, the *average* number throughout the entire period was 262,496. Among these there were 14,178 cases with 1963 deaths. These figures, however, must not be taken as indicating the relative susceptibility of German and French soldiers, even under the regulations then in force in each army, for the conditions of the latter were being continually changed. The prisoners were distributed among some twenty or thirty garrison towns, the numbers quartered in each ranging from 1000 to 15,000 according to the accommodation available. Whenever cases of small-pox appeared the rest of the detachment were vaccinated, if need were, as with the Turcos, by force, and the outbreak promptly arrested. Each fresh arrival of prisoners bringing with them the seeds of another outbreak, the work of suppression had to be resumed.

I must reserve the statistics of the French Army to a subsequent article.

THE GERMAN VACCINATION ACT OF 1874.

Another equally false allegation of the anti-vaccinationists is that vaccination and re-vaccination were as strictly enforced in Germany before the Franco-German war as they have been since; that it was the law already in force in Prussia, which she, as the "predominant partner," imposed on the

lesser States, and that the change, if any, in the practice has been towards greater laxity, vaccination having previously been required within the first year, but now before the end of the year of grace following that in which the child was born, *i.e.*, within thirteen to twenty-three months, according as the birth occurred in January or December. Except the last, these assertions are absolutely false. I have before me the Act itself, and Jacobi and Guttstadt's annotated edition, with notices of the local laws that it superseded, and excerpts from the speeches delivered during the progress of the Bill through Parliament. In the introduction they thus describe the position:—

"Vaccination was already a subject of legislative concern in most of the federated States. Legislation had in the great majority expressed itself in favour of compulsory vaccination restricted to the first year of life. Thus in Bavaria, Baden, Hesse, the Grand Duchy of Saxony (Coburg-Gotha), Oldenburg, Brunswick, Sax-Meiningen, Anhalt, Schwarzburg-Rudolstadt, Hamburg, and Alsace-Loraine; in some indeed since the beginning of the century, the single vaccination of infants was the sole duty enjoined on the Local Authorities. Recently a few of these States, as Sax-Meiningen and Anhalt, had made provision for the re-vaccination of children at some later age. In the kingdom of Saxony and in Prussia, the legislature maintained a somewhat different position. In the former State compulsion was wholly foreign to the legislation, and the same was the case in Prussia, at any rate prior to the year 1866, for in the provinces subsequently annexed, viz., Hanover, Schleswig-Holstein, and Hess-Nassau, legal compulsion existed as regards the vaccination of infants, and in Nassau to a limited extent even of re-vaccination. In the kingdom of Saxony, however, as in the older provinces of Prussia, the Government had long endeavoured, and not without success, to introduce among the mass of the people the general practice of vaccination. These diversities in the state of the law, together with the scant attention that had been devoted to the statistics of vaccination, seriously impaired the practical value of the evidence laid before the Imperial Parliament. On close examination so many gaps and such considerable differences were found that all attempts at drawing definite conclusions had to be abandoned."

I have quoted Dr. Guttstadt thus fully to show the gross untruthfulness of the assertion that the Imperial law of 1874 was but the extension to the rest of the empire of that which already obtained in Prussia, a country which Professor Körösi, of Budapesth, ranked with Austria, France, and Holland, as one of the worst vaccinated at that time; England, Scotland, Sweden, and Bavaria, being in his opinion among the best; and Dr. Voigt, of Hamburg, stated that in that city, the only compulsion being exerted by the School Authorities, vaccination was generally deferred until the sixth year, when their attendance at school rendered it obligatory.

Except in Frankfort, re-vaccination, other than that of army recruits, was as wholly optional and as generally neglected as in this country, and there was practically no compulsion in respect of the vaccination of infants. By the law of 1874, vaccination within the second year, and re-vaccination at the completion of the twelfth (unless the child have had small-pox, or been already successfully re-vaccinated within the five years immediately preceding) are enforced under penalties of 20 m. (= shillings) for the first, and to 40 m. or three days' imprisonment for repeated defiance of the law. The proportion of successful evasions of primary vaccination by removal or otherwise than owing to medical certificates of unfitness, is less than 10 per cent. for the whole empire, and quite insignificant in the large towns and populous districts, the percentage evading re-vaccination is 0·6 without and 3·0 with such certificates. These facts are a sufficient answer to the question why we appeal to the evidence from Germany since 1874, and why our opponents refuse to face it. In 1870—2 small-pox ravaged the whole of Europe, and having practically exhausted the susceptible material, all countries alike enjoyed a respite for a few years. In 1874 Germany turned over a new leaf, adopting compulsory re-vaccination of all children as they entered on their thirteenth year, while the other nations continued much as they were before, and with the result that while everywhere else epidemics have recurred with their accustomed regularity, there have been none in Germany, while even isolated cases and small local outbreaks have become rarer year by year, as the proportion of the population who, by having

* Since 1884 many years have passed without a single death.

Before 1874 the mortality had long been higher in Prussia than in Austria, but since that date it has risen in Austria to a higher figure than previously, while in Germany it continues to decrease, and the great towns enjoy almost entire exemption.

passed their thirteenth year when the Act came in force, escaped its essential provision, that of re-vaccination, is growing less; and even these cases are invariably the consequence of infection introduced from neighbouring countries.

The sanitation hypothesis is a hollow sham. I grant that the poorer classes in Italy are dirty, ill-feed, and worse housed, but there is little difference between the Germans and ourselves. The fallacy of the argument is, however, palpable when one compares the eastern provinces of Prussia, the population of which is not German but Polish, poor, ignorant, and dirty, and like the peasantry of the West of Ireland in habits and diet, enjoying, but for occasional introduction of infection from over the Russian frontier, an exemption equal to that of the other districts, with the Dutch, whose cleanliness and thrift are proverbial, but who with vaccination perfectly optional and generally neglected suffer from small-pox in the proportion, compared with Germany, of 620·1 !! Vaccination would have been compulsory in France had the Bill introduced in 1881 by Dr. de Lionville become law, but it did not pass beyond the first reading, and the subject was dropped, save for the issue of a circular on the advantages of vaccination, which was described as "the duty of every good citizen."

As to the statement that the French army was as well vaccinated as the German, it is true that since 1857 all young soldiers had, according to Dr. Legouest, been vaccinated, but this regulation did not extend to the Garde Mobile, which constituted so large a part of the army in the war of 1870—71, and the quality of the vaccinations performed may be judged from the fact that ten years later (*l'Hygiène en France par les Drs. Napias et Martin*, 1882) the authorities congratulated themselves on the great improvement effected since the war, as shown in the high proportion of successful vaccinations, which had reached 30 or 35 per cent. What could it have been before? A German army surgeon who failed in two out of every three cases of men who had not been vaccinated since infancy, would be curtly informed that his Majesty could dispense with his services, since not more than one failure in ten could be allowed. So far, then, from every French soldier being vaccinated, the truth is that only one in three is so now even in the line; and that at the time of the great war the proportion was much less, while of the Garde Mobile, especially the Breton regiments, which furnished some of the best troops engaged, the great majority were wholly unvaccinated. Between 1875 and 1879 there were, according to M. Marveau (*Jour. d'Hyg.*, February 21st, 1884), 4273 cases of small-pox in the French army with 363 deaths, equal to 5 per cent.; while in the German there were from 1873 to 1878 only eighty-five cases with no deaths. In 1879 an outbreak occurred involving seventy-three cases, not one of which was fatal. The explanation is, that while nearly every German soldier was re-vaccinated, only one in the three of the French soldiers was; for an unsuccessful vaccination is no vaccination at all, and leaves the individual precisely where he was before.

In this article I have exposed the falsity of certain statements which the anti-vaccinators persistently advance: (1) That the statistics of small-pox in the German army during the war exist only in the imagination of the advocates of vaccination; (2) that the French army was, or is, as thoroughly vaccinated as the German; and (3) that vaccination was as universally and strictly enforced in Prussia, if not throughout Germany, before the war, as since, and that the Act of the Imperial Parliament of 1874 was but the application of the Prussian law to the whole empire. These are not questions of inference, but of fact, which may be, and which I have determined by reference to Statute-books, and the official statistical reports of the respective countries, so that the repetition of these falsehoods will be wholly inexcusable.

Notes.

THE outstanding event in London last week was the speech of Lord Salisbury on the problems of the future government of London. The importance of the question in the minds of the Government has already been indicated in the speech of the Prime Minister at the Albert Hall some two months ago; and the position it occupies in the eyes of the people of London was sufficiently evinced by the size and the influential character of the deputation that waited on him and the Duke of Devonshire at the Foreign-office on the 2nd inst. The delegates present represented no less than twenty-two different parishes, with a total population of 2,600,413, and a rateable value of £20,638,260. Mr. Wheeler, Q.C., who introduced the deputation, pointed out how the population represented was equal to that of Liverpool, Manchester, Birmingham, Leeds, Sheffield, and Bristol combined, and the rateable value exceeded that of all those great towns by about 50 per cent. Backed by such a mass of popular opinion, which has been steadily growing in strength for the last two years, the views of the deputation were bound to carry the greatest weight.

A WIDESPREAD impression has prevailed ever since the date of Lord Salisbury's Albert Hall speech that the Bill that the Government propose to bring in will practically destroy the County Council, which was their own creation in 1888. The deputation made it very clear that they had no such aim, and Lord Salisbury in a few sentences brushed aside the very suggestion. The desire of the Government, on the contrary, is to increase the usefulness and the efficiency of that body by reducing the sphere of its labours, which is already too great. Many of the powers of the County Council may with advantage be transferred to the smaller municipalities to be created within its area. But it is fully recognised that many of its powers cannot be so transferred, but must remain as they are at present. The control of the Fire Brigade, main drainage, bridges, &c., must be left with the great central body. Indeed, as Lord Salisbury said, so far from the power or the dignity of the London County Council being minimised, he owned that, owing to the physical conditions of the metropolis, it was necessary that the Council should possess larger powers than other County Councils did.

WHEN it comes to be a question of what powers are to be devolved and how the rates will be

affected, problems of some difficulty at once arise. The Duke of Devonshire, while acknowledging his entire sympathy with the objects of the movement, looked at the subject from a practical point of view, and pointed out to his hearers many of the difficulties with which it is beset. He will have charge of the Bill when it is introduced, and it was therefore inevitable that the practical details of the measure and the shape that it will have to take should occupy the greater share of his attention. In the Privy Council-office, where municipal charters are issued, he has had considerable experience of the difficulties that attend the readjustment of powers even in the case of provincial boroughs; and such difficulties he could foresee would be as nothing to those which would arise in the case of the readjustment of powers in the metropolis.

One note struck by Lord Salisbury deserves special attention, and that is the growing tendency for the London County Council to be dominated by party politics, against which he uttered a word of warning. His desire was, he said, that it and all other County Councils should be as little concerned with general politics as possible, but should devote their whole attention and power to the adequate performance of their duties. The wonder is that a view which is so plainly dictated by common sense should require to be enunciated at all. It is unhappily too true that, governed as London is at present, a singular degree of apathy pervades the people regarding all municipal questions, and the only possibility of giving life and interest to the elections is by importing the heated air of politics into them. The view of the Government is that a remedy to this apathy will be found by the adoption of a system of devolution such as obtains in France, whereby not only will municipal efficiency be increased, but the affairs of each municipality will be brought more closely under the observation of the citizens, and municipal government will become more a matter of constant discussion and interest, and that will lead to a more healthy and vigorous condition of public life.

The first annual meeting of the Council of the Prince of Wales's Hospital Fund was held at Marlborough House last week, under the chairmanship of His Royal Highness. The Report of the Executive Committee, showing how the money collected for last year had been distributed, was adopted, and various resolutions were subsequently moved and carried. Of these the most important was one proposing the appointment of a Committee of Inquiry, "to visit personally and examine the various hospitals of the metropolis, with a view to ascertaining their present condition, needs, and merits, for the allocation of the funds received during 1898." The object of such a Committee is, of course, to secure that the assistance of the Fund is given to deserving hospitals only, for which alone the Fund was designed: and for that purpose careful inquiries, in many cases necessarily of a delicate nature, are essential, the results of the inquiries being in all cases kept strictly private.

The progress of the Local Government Board inquiry into the Maidstone typhoid epidemic is, as might have been expected, arousing a great deal of public interest. The inquiry is being conducted by Mr. James Stewart Davy, Dr. Theodore Thomson, and Mr. George Waller Willcocks, and a considerable array of counsel is engaged. The evidence had last week included that of Mr. Adams, Medical Officer for the borough, who said that he thought there was conclusive evidence that the Farleigh water was the cause of the epidemic, for 107 of the Barming Asylum patients were stricken with typhoid, and none but Farleigh water was used at that institution. It was impossible, in Mr. Adams' opinion, that the Maidstone drains should have caused the outbreak at the asylum, as they did not extend to there. He had never heard of a case where a typhoid epidemic was caused by the insanitary condition of a town, his experience being that the usual mode of propagating typhoid in an epidemic form was either by water or milk, and he was satisfied that the Maidstone outbreak was not caused by milk. He added that he had proved that the Farleigh water had poisoned over 1900 persons, nearly the whole of whom had drunk that water.

Dr. Washbourn, of Guy's Hospital, also confirmed his previous bacteriological reports to the Town Council that there was positive evidence of animal pollution in the samples of Farleigh water taken on 18th September. He did not actually find the typhoid bacillus, but pointed out that it was very rare that such discoveries were made. On the other hand, Dr. Sims Woodhead, lecturer on bacteriology at the Royal College of Physicians and Surgeons, who was called as a witness for the Water Company, said that he had analysed various samples of Farleigh water taken on 5th November, but had failed to find any traces whatever of typhoid or animal pollution. He had advised the company to sterilise the water mains merely as a precautionary measure, and to restore confidence among the townspeople. Dr. Tew, Medical Officer of Health for the West Kent Combination of Rural District Councils, gave evidence for the Maidstone Rural District Council, and stated it as his distinct opinion that the fever was conveyed by the water and not by the drainage. He said that a bacteriological examination he made of a sample of the Farleigh water taken on 22nd September disclosed the presence of the *bacillus coli*, though he could not trace the typhoid bacillus. The water was also polluted with fœcal matter. He added that the results of his examination had been confirmed by Dr. Foulerton's report.

The inquest on the body of Mrs. Jones, the head nurse at Hatton County Lunatic Asylum, who died recently under mysterious circumstances, as reported in our "Notes" last week, was opened on the 29th ult. Dr. Miller, the Medical Superintendent of the Asylum, adhered to the opinion he had previously expressed, that the epidemic which had excited so much public attention, and from which the deceased had died, was merely a form of influenza, and had nothing to do with poisoning, as has been alleged. In Mrs. Jones' case it had been aggravated by chest and kidney complaints. The suspicion which has been aroused in the neighbourhood has, however, been by no means allayed, and the Coroner has deemed it necessary

to adjourn the inquiry until the 25th inst. for an analysis of the contents of the stomach of the deceased. That test may not be quite infallible, but it is quite probable that it will determine the true character of the outbreak.

A VERY painful scandal has arisen in connection with Darenth Lunatic Asylum. One of the women inmates of that institution became pregnant and died during her confinement some months ago, under circumstances that called for the strictest investigation. It was the duty of Dr. White, the medical superintendent of the asylum, to report the matter officially to the Asylum Committee; but, instead of doing so, he merely reported it to the Chairman of the Committee, leaving it in his hands. The chairman called a special meeting, and he and the clerk were directed to examine into the case. No report of the case was made by the doctor to the proper authorities until he recorded the death, and no *post mortem* examination appears to have been made, though the rules of the Asylum required this to be done. It was no doubt an error of judgment on Dr. White's part, but it was also a grave dereliction of duty; and the Metropolitan Asylums Board has marked its sense of the gravity of the omission by calling upon Dr. White to resign forthwith. Considering that he has been Medical Officer at Darenth for sixteen years, it seems an extreme course to adopt, but the Board felt that if they were to pass over such failures in the discharge of duty on the part of their officers, the responsibility of the members of the Asylums Board would be rendered quite intolerable, for public opinion is extremely sensitive on such matters as the regulation of our asylums. The recommendation was carried by a very large majority, as was also a resolution censuring the Darenth Committee for failure in the discharge of the duty entrusted to them.

VERY distressing accounts are to hand last week of the spread of the plague in Bombay. The death-rate, which on 20th January was 95·29, rose during the following week to the appalling figure of 108·7 per 1000, the normal rate being 45·37. The exodus is increasing, and is reaching such a pitch that the Government have felt themselves compelled to erect quarantine barriers everywhere in order to check it. The anxious desire of the Authorities is to prevent the flight of the panic-stricken natives, carrying with them the germs of the disease all over Western India. Fresh detachments of troops have been called out on plague duty, both to draw the sanitary cordon closer round the afflicted city and to assist in the cleansing and demolition of infected premises. Lord Sandhurst, the Governor, fears that the plague will increase rapidly within two or three weeks' time, in spite of all these precautions, and that penning up of the large population is likely to develope a panic; and so he has issued an order calling upon affected persons to remove themselves and their families to a camp across the harbour, on the group of islands including Hog and Elephanta Islands.

THE anxieties of the Government have been added to by a recrudescence of the plague riots. The panic caused by the spread of the epidemic, and the unreasoning aversion to the sanitary regulations for suppressing the infection, have roused popular fanaticism to such a dangerous pitch that serious riots have broken out in several places. At Nasik the mob broke into the buildings connected with the Medical Administration, attacked the officials with ruthless fury, and murdered the doctor in charge. They also wrecked all the sanitary sheds, demolished the Post-office, and cut all the telegraph wires, in order to prevent news of the disturbance from spreading. It is feared that similar riots may break out any day in Bombay itself. It is a dreadful state of affairs, and the task before the Government is one which will call for the utmost coolness and judgment. At present they are doing all that is humanly possible to stay the ravages of the disease; but in spite of their utmost efforts, they seem unable to cope with it.

NOTES ON

PRACTICAL SANITARY SCIENCE.

BY WILLIAM H. MAXWELL.

Assistant Engineer and Surveyor, Leyton Urban District Council, Author of "Drainage Work and Sanitary Fittings," "Ventilation, Heating, and Lighting," &c., Certificates of the Association of Municipal and County Engineers, and Sanitary Institute.

No. 48.—REFUSE DESTRUCTORS.

(Continued from page 112.)

Mr. B. D. Healey, in 1894, patented a new type of furnace[126] with boiler, and has very recently taken out a further patent for "Improvements in refuse furnaces and steam boilers, and setting boilers in connection therewith."[127] These latter improvements relate to the type of furnace and boiler referred to, and are illustrated in Fig. 12, of which the following is the description:—

Below the ashpit of the furnace is a tunnel for wagons, which receive the fine ashes from the fire-grate. At the back of the ashpit is the blast flue, in which is the main shaft with eccentrics for driving the cams of mechanical grates when such are used.

The furnace arch has two sets of ports for passing the gases into the flue, which collects the gases from several furnaces. Either the dampers of the front ports, or of the back ports may be fully open, or each may be partly open to suit the requirements of the furnace.

In the arch of the flue are openings through which the heated gases pass to the water-tube boilers, which are set over the furnaces and clinkering floor, or at the ends of a rank of furnaces, as may be most convenient to users.

The heated gases pass over a bridge, and downwards to the flue outlets, which are connected to the main chimney flue, and the velocity of the current passing thereto is regulated by a damper in each outlet.

The boiler may have one water drum at each end, but it is preferable to have sectional headers which take two tiers of water tubes each, as shown in the accompanying figures. The ascension pipes pass upwards to about 3in. above the

---

126 Patent No. 12,179, A.D. 1894.
127 Specification patent No. 14,698, A.D. 1896.

water level of the steam drum, and the downflow or siphon limb tubes start about 3in. below the water level of the steam drum.

Instead of making the downflow tubes as described above, a dam may be put in water space of steam drum to keep back the mud and deposit, and instead of the ascension pipes extending to above the water level of steam drum, another dam may be put to about 3in. above the water level, and at such distance from the front end of the steam drum as will allow of the ascension pipes delivering their water and steam into the separator, which is formed by the latter-named dam.

The upper header has two connecting tubes for downflow of water from the steam drum, and the middle and lower headers have two ∩ connections each, or they may have two separate connections each to the steam drum, arranged in a similar way to those at the front of headers. All the tubes connecting the middle and lower headers with water space of the steam drum are provided with two universal joints for security and handiness of fixing.

The headers are by preference all made of the section indicated in Fig. 12 for front headers, which form a vertical face when set up as shown, but they may also be of the rectangular form as intended for ack headers. The usual pockets on the steam drum for receiving the tubes which connect with the headers are not required, but in place thereof single or double seats are attached to the drum and the tubes are expanded into them.

The inclination of the steam generating tubes between the lower headers and the upper headers does not require to be greater than 1 in 8, and should not be less than 1 in 12.

There is a greater number of tubes in the width of the setting than there is in the height, and this system is adopted whether the boiler is made larger or smaller than the one illustrated, so that in every case a maximum area of flue space is obtained, and a minimum rate of velocity of the gases without retarding the induced currents at the furnaces, and the latter may be worked with or without forced blast, or alternately with and without.

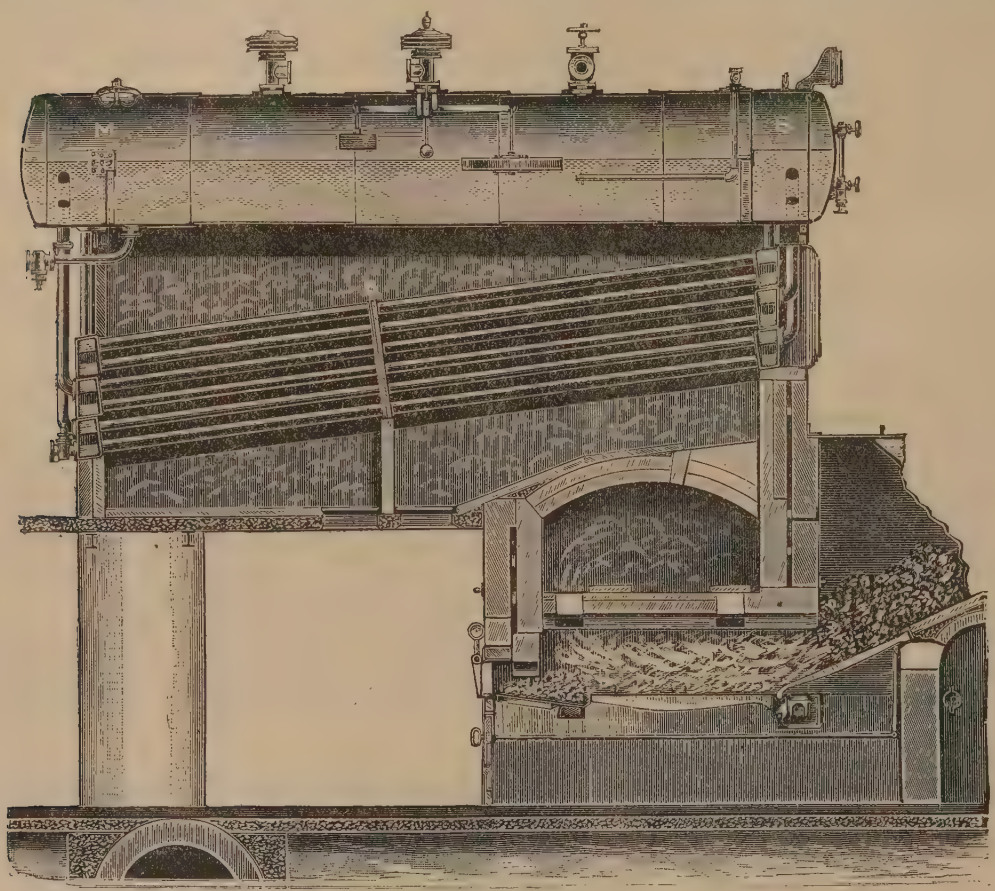

Fig. 12.—Healey's Refuse Furnace, showing boiler setting.

The charging entrance of the furnace springs at the same level as the furnace roof, and the crown of the arching over this entrance and furnace is finished evenly and level from end to end. The entrances for clearing out the dust from the boiler chambers are indicated in the figure. When a furnace is shut off for repairs, suitable close-fitting iron covers are laid over the gap in the ashpit bottom.

When the boilers, as shown and described, are

used for solid fuel firing the heated gases pass up and down twice before reaching the outlet flues. In every case the walls of the boiler setting are provided with the usual dust-cleaning slots and doors for steam jets to operate in.

The novel points claimed by Mr. Healey in connection with the above invention, are :—

1. Constructing refuse furnaces with arches over same, having a level line of springers, and with two sets of outlet ports, as shown.

2. Constructing such furnaces with a tunnel for ash wagons, large blast flue, and a collecting and distributing flue for heated gases.

3. Setting water-tube boilers over such furnaces, or at the ends of ranks of furnaces in the manner shown, or any mere modification thereof.

4. Building water-tube boilers with a greater number of tubes in the width than in the height of the setting.

5. The method of forming the water headers at the ends of the generating tubes of the boilers.

6. The method of connecting the ascension and downflow tubes to the steam drum and water headers.

7. Forming dams in the steam drum or projecting the ascension and downflow tubes thereinto.

8. The system of catching the mud and deposit by dams or their equivalent projecting tubes in the steam drum.

THE SANITATION OF DOMESTIC BUILDINGS.

By Frank Latham, C.E., M. San. Inst., &c., Assistant Surveyor, Borough of Margate.

CHAPTER III.

VENTILATION OF DRAINS.

The usual mode of ventilation of house drains is by means of metal pipes attached to the highest part of the drain and carried up in the open air to an elevated position, an inlet being provided at the lowest part of the drain. By this means relief is given to the pressure, and a current of fresh air is induced to course through the drain, removing offensive and impure odour.

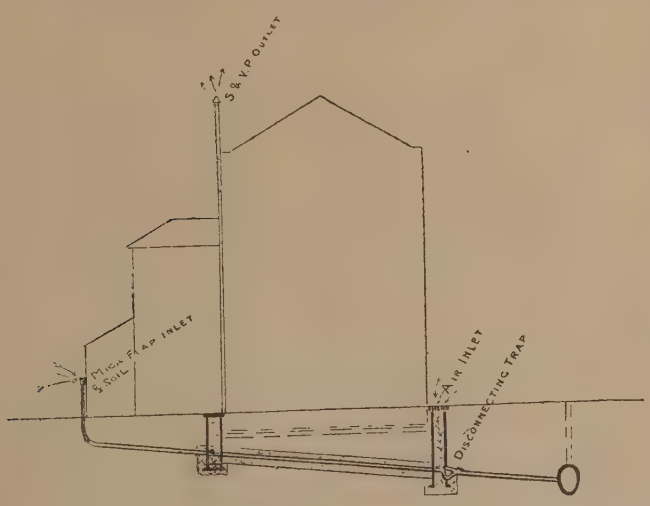

Fig. 22.

It is of the utmost importance that drains should be well ventilated, as the more open they are kept the less likely they are, not only of becoming foul, but for the air to find its way through any fracture or defect that may exist, into the house, it being easier for it to make its escape into the open air through an unobstructed ventilation opening.

The number of inadequate and unworkable methods of house drain ventilation that from time to time have come before the author's notice is considerable, to say nothing of the dummy ventilators which every now and then are discovered. In some cases every endeavour has been made to effect a good system, which on testing has been found a non-success.

To carry out a good and effectual mode of house ventilation requires something more than the sticking up of a pipe, or the results may be even more pernicious than the evils it is intended to prevent.

In ventilation of house drains there should be at least one inlet and one outlet pipe for the purpose of extraction. The inlet should be placed low down, and at the foot of the drain, the outlet being taken off the highest part and carried up some height, as by so doing the movement of the column of air, supposing the surrounding circumstances to be favourable, will be regular. The fresh air being admitted at the inlet, which on becoming warmed and therefore expanded and lightened, will rise up to the highest part of the drain and up the ventilator, the latter assisting its velocity by the current of air passing over its open end. The air inlet is generally fixed in conjunction with the disconnecting trap a contrivance by which the house drain is cut off from a direct communication with the sewer.

In cases where the closets are in the centre of the building, *i.e.*, between the main building and back addition, the principal outlet can be taken up at this point, but should the drain extend further on as is the rule, to pick up sink gullies and outside w.c., &c., another ventilation pipe should be carried off the extreme end, and terminate lower down, away from all openings, into the house. This will then act as an inlet for that part of the drain, and the one outlet will do service for the two inlets. (Fig. 22.)

Outlet ventilators can be in connection with the main soil pipes, which must be carried up full bore without any bend, if possible; terminating well above any windows, and away from any chimney or other openings. It is, however, preferable, for the purpose of ventilation, to have a separate outlet pipe in connection with the drains, as when the soil pipe is in use the ventilation is affected, and further, it is not always necessary or soil pipes to be as much as 4in. in diameter, but outlet ventilators should not be less than that size, and the dryer they are kept internally the better they work. The separate outlet and the soil pipe can, as a rule, be fixed side by side, and the latter, which must always have an open

end above where the top connection is made, instead of being carried up, can be turned into the side of the former—an expedient which would also apply to anti-syphonage pipes. No soil pipe should be trapped at the foot when disconnecting traps are used.

Where more than one closet discharges into a soil pipe, which, as before stated, should always be carried up full bore, and caused to ventilate above the roofs of the houses, the out-go pipe between trap and soil pipe of all closets should be connected to an anti-syphonage 2in. in diameter, and the same carried up full bore abreast of the soil pipe and terminated into

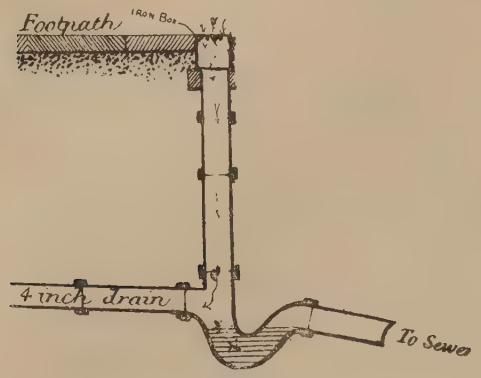

Fig. 23.

its side above the top fitting, unless other provision is made as before mentioned. The principal inlet ventilator at the foot of the drain should always be placed close to the disconnecting trap and on the house-drain side, a junction as a

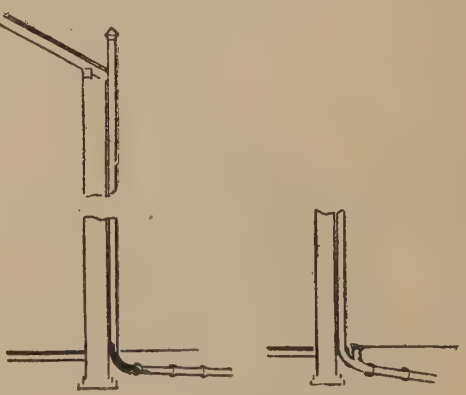
Fig. 24.

rule being provided on the trap for that purpose, which should be carried up in stoneware glazed pipes, properly jointed together, and terminating on the edge of the path, and the open end covered with an air inlet and dirt-box grating, which should be fixed level with the path. (Fig. 23.) This is the method adopted by the Local Government Board in their "Model Bye-laws," and is, in the author's opinion, having watched the results of some thousands of cases of its employment, very satisfactory.

In some cases of drainage, more particularly in connection with cesspools, the mica flap valve air-inlet ventilator is used. (Fig. 24.) This inlet is supposed to work automatically by the valve opening to let the fresh air pass in, and closing immediately any back-pressure takes place. It is well, however, not to trust too confidently upon this action being permanently maintained, as the mica valves are not always to be relied upon owing to their getting out of shape, and not properly closing, or in some way becoming damaged. Should the valve be in good order, the proper fixing of it also has much to do with its effective working. The valve box should be fixed a little inclined towards the front, till the flap is quite closed by its own weight. By so doing the valve will not remain open, when not admitting air, for the escape of any foul smells from the drain.

The outlet ends of ventilators should, in cases where there are no houses, chimneys, or trees at a greater height anywhere near that might produce a down-draught, be protected from birds building nests in them, by a wire cage; but should there be any danger of down-draughts a good open cowl, finished off to the pipe, with wire work, or other similar contrivance, is necessary to prevent the wind blowing down the outlet, and sending occasional puffs of air up the inlet.

Ventilation pipes should have as few bends as



Figs. 25 and 26.

possible, but in cases where these unfortunately cannot be avoided they should be long and slow, so as not to impede the air current, and to prevent as much as possible any rust, incrustation, or other foreign substance from finding a resting place in them. It is also important that ventilation pipes, when independent of a w.c., or flushing arrangement to keep them clean, should be provided with an inspection eye at the foot, to prevent their becoming stopped up with rust, &c., falling down the pipe, and lodging at the bottom. (Figs. 25 and 26.) It is preferable in such cases to use lead pipes to iron as they are not subject to rust or scale.

Traps under lavatory basins and scullery sinks should be ventilated by inserting 1½in. anti-syphonage pipe at the top of trap outlet, and for single wastes carrying it through an external wall, leaving the end open in the air. In the case of a range of basins, the trap under each basin should be vented in precisely the same manner as the latter and carried into one common 2in. anti-syphonage pipe, terminated in the external air. All ventilators should be connected above the water-line in the pipes; if not, when the drain is in use, the vent opening may be water sealed, and thereby rendered useless.

WHY THE SUPERFICIAL SOILS OF CITIES ARE UNSANITARY.

DR. ROBERT BARNES, who as long ago as 1855 was a health official for a part of London, treats, in a contribution to the *Scalpel*, of the dangerous properties of the superficial soil of cities, the careful future investigation of which will solve some of the mysteries of high civic mortalities. We agree with him that we do well to labour with the outstanding problems of water-supply, but as they will presently be mastered, the problems of the soil will become urgent, and, as they too are solved, life-saving will begin in good earnest. Dr. Barnes says :—"One of the most striking examples of the influence of soil, and soil governs water and air, is the generation of ague. Ague was at one time endemic in Shoreditch, but it has vanished. So we may reason that unhealthy sites may be made healthy by care, but it is not less true that sites, naturally the most salubrious, may by neglect become pestiferous and deadly. I showed that we were chiefly concerned with the soil to the depth of 30ft.

"Proceeding from the surface we had a bed of variable thickness, commonly called 'made earth.' It is chiefly an artificial stratum. The proportions of 'virgin soil' to that of common earth had been reduced to a very insignificant amount. The great bulk was made up of refuse of every kind. . . . This upper stratum so constituted had been further polluted, and its noxious qualities intensified, by innumerable perforations for cesspools, and constant saturation from defective sewers and drains, the poisonous emanations from gas pipes, and every conceivable abomination resulting from the off-scourings of a population of 25,000. This layer of foul stuff, or pest-stratum, as it may appropriately be called, varied in thickness from 1ft. or 2ft. to 16ft. or more. This description of the pest-stratum is a very important contribution to geology. This last stratum, the work of man, has to be cleared away. This done, geology reverts to its primeval natural purity. Another observation may be pardoned. If this pest-stratum, laden as it is with putrescent matter, could be kept dry, it would be comparatively harmless. Moisture is a necessary element for the evolution of its pestiferous properties. Hence good surface drainage is not less necessary than deep drainage.

"And we may see a happy illustration of this in the present condition of the city and the more perfect districts of London. The paving and other means for securing quick surface drainage not only lessen the emanation of foul air from the surface, and from the soil beneath, but they also promote the dryness of the air. The relative humidity of the air in London is often less than in the country. This is especially marked at night. There is little or no dew. The dry surface gives off no moisture for precipitation. And so we get in London the luxury of clear, dry, fresh air at night to a degree hardly known in many parts of the country. Doctors who have experience of night work have found this out. A practical lesson from this is : That windows may often be opened at night in London with benefit, when in the country, where grass is near, the practice is fraught with danger. I have had many proofs of this in country consultations.

"To secure this surface drainage and cleanliness to the greatest extent it is essential that the material for pavements be solid and impermeable to moisture. Flagstones and asphalt fulfil these conditions. Wood pavement, pleasant as it is in some respects, does not. It absorbs damp filth and gives off foul air and dust. The population actually living on the bosom of the Thames, whose every breath is a distillation from its water, is not especially liable to fever ; not so much so, indeed, as the population whose dwellings skirt the banks. And this littoral population, it must be borne in mind, is exposed not only to the malaria arising from the banks, but also to that same class of pernicious influences attached to bad sites and badly constructed houses, which are found alone sufficient to generate fever.

"Few of the seamen who filled the medical deck of the Dreadnought contracted their illness on the river under circumstances which can be connected with the state of the waters ; and of these few it will be found that the illness of most could be traced to cold, wet, exhaustion, bad food, drinking bad water, and over-crowding in the close ill-ventilated forecastles of unhealthy ships. Most erroneous assumptions still continue to guide the exertions of those who are most earnest in favour of the present scheme of what is called the dis-pollution of the Thames. I had studied the Gulf Stream as it flows in a distinct current across the Atlantic ; I had seen the Plata propelling its stream of fresh water unmingled many miles into the ocean ; I had traced the confluence of the Rhine and the Main, whose streams are coloured, one red, the other green, running on side by side, two rivers in one bed, and I concluded that the great sewage stream would hold its course, a concentration of pollution.

"Sir John Simon, in his admirable reports, expressed conclusions in harmony with the above, and with the evidence adduced in my observations on the Thames, read before the British Association at Dublin. In this memoir, based upon examinations of the Thames water, of which samples were taken weekly during a whole year, at high and low water, from alongside the Dreadnought, I was assisted in the chemic side by Odling, and Hassall in the microscopic side. During the construction of the easternmost main sewer I had an opportunity, I will not say of enjoying, but of experiencing a festivity under conditions which few excepting professional sewermen can appreciate. I accompanied a Committee of my Vestry and the Surveyor in an official survey of the sewer. We descended into this subterranean canal by a hole near St. Luke's Asylum, walked along as best as we could, breathing the balmy sewer air, to a point at the East End of London, where we emerged.

"It is needless to say that as a safeguard against accidents, we took with us a supply of alcohol ; and, to make our visit and report more picturesque, we stopped on our way and had lunch with what appetite we could muster. This experience taught us, I hope, to look with indulgence upon the occasional breach of the law of temperance by professional sewermen. On coming into the free air above I felt as I fancy Dante felt on passing from the Inferno into Paradise. No one was the worse for the adventure."

THE PAVING OF YARDS.

In reading over the report of Dr. Dudfield, Medical Officer of Health, Kensington, we notice that he draws attention to the condition of the back yards attached to some of the smaller houses in his district. Quoting from a draft report of a special committee, he states that they were "struck with the bad state of the yards at the backs of the houses; 'gardens' there appeared to be practically none. The yards, excepting as to a small portion close to the house, are unpaved and undrained. They were littered, in a neglected condition generally, and in many instances filthy with deposited matters of an objectionable character, including ordure, human and animal. Any filth once deposited must either soak into the ground, whence it will return in hot weather laden with germs, or, becoming dried, will pass as dust from the surface into the atmosphere."

Dr. Dudfield draws attention to the power possessed to compel owners to properly pave the yards, and goes on to observe, "I venture to think that more would be done in this direction, by Sanitary Authorities generally, if due weight were attached to the hygienic importance of cleanliness in the surroundings of dwelling-houses; and I am glad to have the opportunity of enforcing my own feeble utterances on the subject by citation of the views of the Medical Officer to the Local Government Board, who in a recent publication* refers to 'the circumstances of the soil and surroundings . . . favourable to the vitality and multiplication of the typhoid bacillus,' the efficient agent in the causation of enteric fever. 'They are (he states) that the soil should be pervious, that it should be permeated with a sufficiency of decaying (preferably animal) organic matters, that it should possess a certain amount of moisture, and that it should be subject to a certain temperature. And then (he continues) let us consider what means can be adopted to deprive the soil of one or more of these conditions which appear to favour the retention of the vitality and power of the typhoid bacillus, and to prevent that organism from gaining access to the soil in the neighbourhood of human dwellings'; and here my point comes in, the author proceeding to say that, 'to this end he would in the first place advocate the paving of open spaces about dwellings where these open spaces are of small area and are liable to become contaminated with excreta. In this way fouling of, as well as penetration by a pathogenic micro-organism into the underlying soil, is practically prevented.' He adds that 'it is well known, not only that the paving of yards about small cottages and tenement property in towns has in its results been shown to be a public health measure of first importance, but also that the nature of such a measure has depended largely on the use of a form of pavement which really ensures permeability.' The reference to this branch of the subject concludes as follows:—'Where open spaces about dwellings are large, and where organic pollution of surface soil is practically absent, we may rely, as inhibitive of this (typhoid) bacillus, on the influence of sunlight and of alternating weather; but in our towns the conditions have become too artificial, and the open air about dwellings has become too restricted, for us to hope that under the unnatural conditions which have been induced by urban aggregations of dwellings, we have any right to expect the full benefit of Nature's remedies.'"

* "Soil and Circumstance in their Control of Pathogenic Organisms," by Sir Richard T. Thorne, K.C.B., F.R.S., whose observations, it may be mentioned, are based largely upon investigations made for the Medical Department of the Local Government Board, by Dr. Sidney Martin.

SEWAGE PURIFICATION IN GERMANY.

The city of Spandau, near Berlin, discharges its drainage into the river Havel, which in turn empties into the Elbe, and the number of cities located on both rivers below Spandau rendered it most desirable that the sewage should be purified before entering the stream. This subject was considered when the present sewerage system was planned in 1890, and since 1895 the purification plant has been constructed, and is now in successful operation. An excellent account of the method, including details of construction and cost, is given by Herr Pfeffer in the *Gesundheits-Ingenieur*.

The general method adopted is that of clarifying the sewage by use of a solution of chloride of iron, which precipitates the albuminous matter and phosphoric acid, and also checks the formation of sulphuretted hydrogen and sulphide of ammonium, thus removing much of the foul odour. Further purification is effected by the addition of carbon in the form of finely-powdered lignite or brown coal, and a proportion of milk of lime is also added to assist in the precipitation.

The chloride of iron solution is cheaply prepared by treating bog iron ore with crude hydrochloric acid, and this solution is used in the proportion of fifty grammes to the cubic metre of sewage, while about three times as much milk of lime is added. The lignite breeze is finely ground in a mill and mingled with water to the extent of 12 to 13 per cent., forming a liquid of about 7 deg. Beaumé density; and this is added to the sewage in such quantity as to correspond to about 1·5 kilograms of coal dust to the cubic metre of water. Instead of chloride of iron, the oxy-sulphate of iron may be used, in the proportion of 200—300 grammes to the cubic metre of sewage. The liquid is then passed into suitable settling tanks, from which the solid matter is drawn off from time to time by a system of suction chambers, and delivered to a filter press, where it is compressed into blocks suitable for burning.

It is found by experience that, for every 100 parts of solid matter added to the sewage for purification purposes, 160 parts are obtained in combustible blocks from the filter press, so that 60 per cent. of the matter has been abstracted from the sewage.

The plant at Spandau has been constructed in accordance with experience gained with similar methods used at Potsdam and at Leipzig, and in the latter city the investigations of Professor Dr. Fr. Hofmann showed excellent results, so far as the sewage purification is concerned.

HEALTH LECTURES AT KEIGHLEY.

ON Monday evening, the 31st January, Miss Ravenhill, of the National Health Society, brought her series of lectures at the Co-operative Hall, Keighley, to a close with an address upon "The Machinery for Securing Public Health: Our Power Over it."

Miss Ravenhill observed that although it had been well said that local government was at the very essence of national vigour, it was a curious and unmistakeable fact, she thought, that there was no question of importance in which people took a smaller interest than this of local self-government in health matters. The very fact of our retaining self-government carried us back to the days of the Romans, when each town had its municipal body. The whole question of local government in England had taken on a new aspect during the last ten years, but she would ask them to cast their thoughts back for a few moments to some sixty years ago, when the Municipal Reform Act was passed. Those cities which held charters of incorporation at that day had held them for many hundreds of years, but the view with which the municipal councils had been elected became quite lost sight of during the turmoils and wars of the Middle Ages, and they had been chiefly concerning themselves in really fostering abuses of many kinds, financial as well as administrative. After the passing of the great Reform Act of 1832, which swept away so many pocket boroughs, there was time to turn attention to the reform of municipal corporations, and the Act of 1835, constituting municipal boroughs upon a model basis, resulted. It was strange to recollect that only sixty years ago large towns, such as Manchester and Birmingham, had no charters of incorporation, and that their system of local government was carried on in a more vague and perfunctory manner than could be found in the most remote country village to-day. The number of towns which had since applied to the Privy Council for a charter of incorporation was 125, and the total number of municipal bodies now in existence was 308. Miss Ravenhill went on to speak of the relations and duties of the Local Government Board, the County, Town, District (Urban and Rural) and Parish Councils, and she pointed out that women had no right to sit on Town and County Councils. She hoped, however, that they would soon gain that right, and she thought the case in regard to the County Council was especially strong, seeing that this body had to deal with the lunatic asylums and reformatories, and thus had the management of women and children entrusted to them. The lecturer deeply regretted that women did not exercise their voting powers in local elections as regularly as they ought to do, and she contended that they ought to fulfil their obligations, because the right to vote carried with it the responsibility. She afterwards alluded to the need of women Inspectors, and to the duties of Medical Officers and Sanitary Inspectors, and described the essentials of a model town—clean streets, public baths and wash-houses, parks, libraries, asylums, hospitals, &c. In conclusion, she dwelt upon the standard of sanitary duty, and showed how the application of knowledge, self-help, and sympathy to these questions would enable much to be done towards the general well-being.

THE DETECTION OF PLUMBING DEFECTS.

FOR several years Edinburgh has had its unofficial system for the expert sanitary examination of dwellings. There is now in New York City, a somewhat similar undertaking, under the name of the Building and Sanitary Inspection Company, and they "offer their services to those who live in houses, for the discovery and correction of causes of unhealthfulness in the appointments and environment of the dwelling." A few years ago one of the most aristocratic apartment houses in the neighbourhood of Central Park experienced an invasion of diphtheria, and though there were several victims in different rooms, the evidence was nearly conclusive, that it had originated in the house: and one bereaved father called in a sanitary engineer, in spite of the protests of the indignant owner who told of how much money he had spent on his ornamental bathtubs and nickel-plated pipes. The expert found that the ventilating pipe that should have gone out at the roof, and extended above it, left off at the lower side of the ceiling of the upper storey and was there replaced by a painted cylinder of wood, which passed up through the storage attic. The noisome exhalations could do nothing else than diffuse themselves throughout the house, and the outraged inmates took the matter to Court, where there was a preliminary hearing; and rumour had it that the murderous owner of the building paid fabulous sums to "buy off" his tenants, and immediately had the most faultless of plumbing put in under the direction and inspection of a competent sanitary engineer. This could not recall to life the dead; and with variations the above is a story that is repeated again and again every year, and tenants and owners are very active after the mischief is done. Had the people who suffered from this landlord's cupidity caused an examination to be made before they rented their rooms, a wholly different result would have been seen. Is it possible that careful fathers who are good business men in other matters, can have been inveigled into attempting to live in houses where eighty in a hundred are defective in the vital point of healthfulness? They were not inveigled, they were simply satisfied with their own judgment, or took on trust the assurances of agents or owners. Many houses were carefully plumbed according to the lights of the time when they were built; but in some the plumbing is worn out, and when a replacement is suggested there is a distinct painful thrill in the pocket nerve of the owner, and he fights it off as long as possible; and where he suspects that there should be a thorough overhauling, but the prospective tenant does not push his inquiries, he soothes his conscience by the thought that "the sanitary condition of a house is, after all, a matter of concern only to the people who live in it." But if neglect is proven and taken to the courts, he wishes he had not waited to be forced to do right. There has arisen in some quarters a tendency to ridicule the idea that the germs of disease are to be found in the emanation from defective pipes, and though there is no doubt a degree of high health and robust constitution that can resist their action, there are thousands who suffer from what for lack of a more definite classification, they call "malaria."

THE SANITARY CONSTRUCTION OF HOTELS.*

By GEORGE VIVIAN POORE, M.D., F.R.C.P.

HOSPITAL architects are quite alive to the necessity of limiting the height and breadth of wards, and of providing windows on both sides, and it is high time that hotel architects began to recognise that public rooms, in order to be decently wholesome, demand an equal attention on their part to the scientific principles of construction.

Hotels, as a rule, are much too high, or in other words, the cubic contents of the building are far too great for the area occupied. The lifts and staircases are often without independent ventilation, and each floor ventilates into the floor above and the floor below. The corridors are often close and dark, and there is seldom any adequate provision for flushing them with fresh air. These huge hotels, where the guests are literally piled in heaps, are most unwholesome. They are the products of cities, and are totally unsuited for climatic health resorts.

They may be a necessity in cities where the price of land is high, but they are not necessary in the country. Nevertheless, I have seen such hotels standing in the middle of ten acres of land, a fact which thereby shows that neither architect or proprietor have been imbued with the principles of wholesome living.

The mediæval colleges as seen at Oxford and Cambridge, and which are, of course, in a sense hotels, appear to me to offer excellent models which the modern hotel architect would do well to adapt to his purposes. They have, as a rule, ample curtilage, the public rooms are big, and often in a building distinct from the living rooms, while the living rooms are quiet and connected with the public rooms by cloisters and covered ways.

In houses destined for the reception of invalids, it is necessary that the sleeping apartments should be quiet, and that the occupant should not be disturbed by his neighbours. In the ordinary flimsily built hotel, the restless invalid is exposed to the annoyance of noisy neighbours above, below, and on either side, while the traffic in the corridor is more or less incessant. All this is obviated by having thick walls and floors, and double doors, such as are common in the mediæval college. It is obvious also, that guests are much less likely to annoy each other, in proportion as the ground area of the building is ample and the height is kept down.

It is, of course, absolutely necessary that the gases of putrefaction should not gain access to the building. If the sanitation be on the unscientific lines which are now almost universal, *i.e.*, the deliberate formation of putrescible mixtures of organic matters and water, and their storage in underground traps, sewers, and cesspools, it is quite impossible to be sure that the gaseous "toxins," the products of putrefaction, shall not gain access to the house. The hotel architect is bound to take as much trouble to minimise the chances of sewer poisoning as does the hospital architect.

In all hotels to which people go for a prolonged sojourn, there ought to be out-door accommodation provided in the grounds, for ladies as well as gentlemen, and there can be no difficulty in ensuring proper seclusion. The gentlemen's "garden" should be reached from the smoking room by a covered corridor, while the ladies' "garden" should in a similar way be approached through the ladies' boudoir. A set of well-designed dry closets such as I have advocated in my books on "Rural Hygiene,"* and "The Dwelling House,"* if properly attended to every day by a scavenger, would certainly be a great comfort to the guests. It goes without saying that no hotel can be really wholesome unless it be provided with garden ground sufficient for dealing day by day with all the putrescible refuse of the house, which should be made to produce flowers, fruit, and vegetables, instead of sore throats and typhoid.

I know of one instance in which the proprietor of a large establishment, without destroying his water-closets, put up "dry closets," as it were in competition with them. These latter were well looked after by the gardener's boy, and in a very little time he was able to abolish his water closets, to save the daily cost and trouble of pumping water, and while the plumbers' bills were sensibly diminished, his land increased in beauty and productiveness.

In an article like the present it is impossible to enter into much detail. Those who may concur in the ideas put forward will get every information in the books alluded to.

Dust and Disease.—It is known that certain diseases are spread through the medium of infectious dust. Consumption, pneumonia, influenza (la grippe), and diphtheria are among the diseases so spread. Some consumptives with localised tubercular deposits are spitting up tubercle bacilli with no suspicion of the tubercular nature of their disease; many other consumptives, some curable under favourable conditions, some less hopeful cases, go to places of amusement though expectorating daily millions of bacilli. The germ of pneumonia finds a habitat in the mouths of many healthy persons awaiting the coming of its opportunity for mischief by the temporary physical deterioration of its host, or by transference to other human organisms whose vital conditions do not confer immunity. Influenza is also an infectious disease spread by the discharges from the nose and throat. The diphtheria bacillus is also found in the throats of some persons who have never had recognisable diphtheria, and it remains some time after the disease in the throats of some of those who have had diphtheria. These disease germs which are found in the sputum of some persons, retain their vitality for quite a while even under the influence of desiccation. The bacillus of tuberculosis in dried sputum retains its full power for harm for a long while. Thus, sputum that has reached the floor, and dried, is reduced into a dangerous infectious dust.

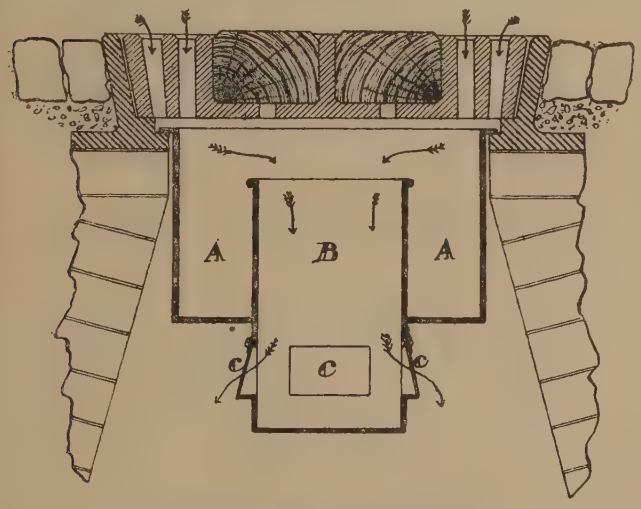
IMPROVEMENTS IN SEWER VENTILATION.

SOME PARTICULARS OF AN INVENTION WHICH WILL HELP TO SOLVE THE PROBLEM.

MR. PERCY MUNROE BEAUMONT, Borough Surveyor, of Maldon, Essex, has provisionally patented an invention the object of which is to provide sewers with means which will allow fresh air to pass into them, but will at the same time prevent the escape of the sewer gases through the opening provided for the admission of fresh air. According to this invention—an illustration of which is appended—the manhole or other opening in the sewer is provided with a dirt basket or receptacle forming a trap for the interception of stones, dirt, or other foreign matter passing through the grating. This dirt basket or receptacle has an inner tube or channel which forms an air passage to the sewer; to the lower end or sides of this passage one or more non-return valves is or are arranged opening towards the sewer. More than one of such inner tubes or channels may be used if required. Air passing through the ordinary grating of the manhole or other opening in the sewer enters the sewer through the valves in the inner tube or tubes. Should the pressure of the sewer gases be greater than that of the air in the dirt basket or receptacle the valves will be closed, and the exit of gases through the manhole or other opening thus prevented.



— Section thro' top of Manhole — shewing combined Air Inlet and Dirt Box in position

Struck by the above particulars of the invention given by Mr. Beaumont in the course of a visit to THE SANITARY RECORD Office, we asked him to supply us with further information concerning it, and in response to our request he wrote as follows:—

"Like, I have no doubt, most other engineers who have open manhole covers in their borough, I am constantly receiving complaints of the great nuisance arising from them, and the difficulty has been to know what to do with them. Some Local Authorities direct their engineers to close the manhole covers, and erect ventilating shafts where possible, whilst others simply have the manholes closed, and provide no outlet for the sewer gases. In my opinion the closing of the manhole covers is a mistake; they should be made to act as air inlets in conjunction with ventilating shafts, gas destructors, or other foul air extractors, and it was to meet this view that I designed my combined air inlet and dirt basket as being a suitable and cheap way of carrying out this object. This invention simply takes the place of the ordinary dirt basket, and can be made to suit any manhole cover, so that there is no expense of altering cover or providing new covers. In many cases the existing dirt boxes could be converted at a small cost. I may add that I have had two or three of these combined air inlet and dirt boxes in use for some time in manholes, which were a great nuisance, and they have proved in every way successful."

Primâ facie, Mr. Beaumont's invention appears to fill a long-felt want, and we do not doubt but what its claims to notice will appeal strongly to every engineer who has had the difficult question of sewer ventilation to contend with.

SEWAGE DISPOSAL.

AT a meeting of the Manchester Chemical Association, held on Friday evening, the 4th inst., in the Owens College, Dr. Grossmann read a paper on "The Treatment and Disposal of Town Sewage." He described the various processes of precipitation, and also the bacteriological treatment. As regarded Manchester, he thought it would be better to continue endeavouring to obtain the best effluent possible rather than carry away the whole of the sewage. He believed, from calculations he had made, that the water remained unchanged in the Ship Canal for probably a fortnight on an average, and if a fairly satisfactory effluent were obtained by proper treatment it would therefore be necessary to disinfect such effluent to avoid putrescence. He proposed to use sulphuric acid for that purpose. Dr. Grossmann dealt with the cost of this. Sixteen grains of acid to the gallon of effluent would be sufficient, and even if the cost amounted to £10,000 per annum it would be cheap to the city, and leave open the question of the adoption of a better scheme if one could be safely devised. He proposed to use lime as the precipitant. He advocated the appointment of a committee by the Society to examine the various methods of sewage purification and report upon them, and thought that it was time the Government took up this important question. Mr. G. E. Davies, who presided, said that some years ago the Society of Arts appointed a committee to inquire into this question. They examined twenty methods, all of which had been described as perfect, but all of them in practical application

turned out to be failures. Mr. Carter Bell said that the experiments made on a large scale with the Salford sewage had convinced him that there was no better precipitant than lime. If from twenty-five to thirty hundredweight were used per million gallons of sewage you got fair precipitation. Afterwards, when the effluent had been neutralised by sulphuric acid, it was fit to go into the Ship Canal.

THE UNSATISFACTORY CONDITION OF REFUSE DISPOSAL IN AMERICA.

REFUSE disposal in America is, according to the *American Engineering News*, in a very unsatisfactory condition. Only a comparatively few cities, remarks our contemporary, have adopted any modern method of disposal, and in many of these the cost of the work is altogether too high, and complaints of nuisances from the disposal plants are frequently made. This deplorable state of affairs is largely due to the fact that as yet the problem has not been approached in so thoroughly scientific a manner as have other problems in engineering. While scores of our most prominent engineers are connected with the development of water supply and sewerage systems, it would be hard to name three engineers of high professional standing who have designed any of the refuse disposal plants now in operation in this country, or taken any essential part in the evolution of such systems of refuse disposal as are now in use.

Nearly all the refuse furnaces in the United States have been evolved by mechanics and artisans of an inventive turn of mind, supplemented by suggestions from small capitalists and sales agents financially interested in the matter. Many of the different makes of furnaces, naturally enough, are but slight modifications of earlier makes. Of refuse utilisation or reduction plants most have been developed by men connected with rendering establishments devoted to the production of grease and fertilisers from old bones and dead animals.

Both cremation and utilisation systems are sadly in need of being taken in hand by competent engineers. The reasons why this has not already been done are various. The most important are that as a class the inventors in these lines have not been engineers at all, and, like the vast majority of inventors, have been so possessed with their own ideas that they have failed to make any real study of the state of the art, further than in connection with trials of their own devices. Both these inventors and the small capitalists whom alone most of them have been able to interest have shunned engineers, partly through jealousy and partly because they did not wish, or thought they could not afford, to incur the expense of consulting them. This has been true of the inventors in both lines, but more true of the capitalists interested in cremation than those who have taken up utilisation processes.

Many of those who have become financially interested in utilisation processes would not of themselves hesitate to spend money for the best engineering advice, but the inventors whom they have backed have declared such expenditures unnecessary and the capitalists themselves often yield to the temptation to work for the speculative profits arising from stock dealing rather than the slower, and perhaps smaller, returns from the business itself. Doubtless the speculative aspects of refuse utilisation processes have contributed largely to keep our best engineers from taking up the subject. They could be induced to give their energies to the development of such systems only when allowed to work along scientific lines, whereas their possible employers have been unwilling to expend money for this purpose, through ignorance or impatience to realise quick profits instead of putting money into experimental researches for future returns. Where speculative ideas have ruled there has been little opportunity for work by an able and conscientious engineer. His services would be desired to bolster up a system, as developed, rather than to search out and remedy the weak points of a system.

In saying what we have we do not mean to convey the idea that there are no good refuse disposal plants or systems in this country. We believe that there are a few which either already have been or are capable of being brought to a high degree of perfection, although most of both plants and systems have many unsatisfactory features. . . . We think it probable that the English type of refuse furnace comes the nearest of anything yet evolved to what a refuse furnace should be.

NATIONAL REGISTRATION OF PLUMBERS.

MEETING AT EXETER.

ON Saturdry evening, the 29th ult., a meeting of the Exeter branch of the Devon and Cornwall Council of the National Registration of Plumbers met at the Guildhall. Alderman Domville presided, and amongst those present were Messrs. W. S. Addiscott and Harvey (Plymouth), Warren, Cole, C. Kerslake, J. F. Ralling, Symes (local secretary), &c.

The CHAIRMAN said he considered it right that as a medical man he should accept the invitation to preside over the meetings of a society which had such far-reaching results in the matter of public health. The work which plumbers did, although hidden, and not gaining so much honour and glory as work that was more open, was of transcendent importance now, when sanitary science required that each little household should be fitted with every possible convenience. Whilst it was all very well for theorists to censure and criticise, that was not of so much value as the work the society had undertaken to carry out of starting from the commencement and giving no consideration to anything but real, thorough, honest practical knowledge. The object which the Plumbers' Company had in view was worthy of the assistance of every citizen. They were twitted that Englishmen were losing a good deal of their old-fashioned handicraft which had made them famous in days gone by. It was something, therefore, for a band of men like themselves to have decided that they would admit no one into their company until he had proved his efficiency.

Certificates were, after the usual declaration had been subscribed to, presented to the following, who had passed the necessary examination: Charles Robert Woodland, Harry Crudge, G. W. Carter, W. J. Cockram, and A. J. Bolt. A hope was ex-

pressed that at the next examination, which would probably be held at Exeter, the district would send up a larger number of men to qualify.

Mr. W. S. ADDISCOTT then read the following paper :—

Some twelve months since it was my pleasure to stand here and say a few words to the plumbers of Exeter on a similar occasion as that which calls us together to-night. We are here to-night also as a proof that we wish to uphold and support the work of the Exeter Committee of which you, Sir, are the respected chairman. It is always gratifying to find our leading citizens willing to forward such movements as ours. On the last occasion we were honoured by having the Mayor of this city in the chair ; this year we are equally honoured by having a member of the Health Committee. Therefore it is with genuine pleasure that I have to thank you, on behalf of the Worshipful Company, for presenting these certificates and presiding, not only at this meeting, but at the meetings of the local committee from time to time. Further, it is our desire to place our work before those who have the administration of the laws affecting the public health, because we feel they are best able to judge of its value.

The Worshipful Company is not the largest, wealthiest, or oldest of the City Companies, but we claim as a set-off to these shortcomings—if shortcomings they be—the Plumbers' Company is one of the most useful, applying its funds for the education of the craft from which it take its name. It gives young plumbers the opportunity of learning the technicalities of their trade, grasping the why and the wherefore work has to be performed in certain ways, without their doing it solely because their fathers did it before them. In furtherance of this idea the company has called into existence a system of examinations for men who are coming up in the trade, and if it were only for this it deserves our heartiest thanks. The method by which the examinations are conducted may be explained in a few words. They are divided into two sections — theoretical and practical. For the latter stage examiners are appointed by the District Council and Local Committees such as you have here. These examiners are taken in rotation as they come on the list, and not only have two masters and two operatives to remain in the examination-room the whole of the time during which the examination is being held, to see that the time of starting and finishing is complied with, but the secretary has to furnish the examiners with a list of the numbers of the candidates on a sheet, upon which remarks on the manner the candidate sets out his work and proceeds to complete his task is done, noting any extra skill that may be adopted. Two men may do the same work with good result, but by the use of technical knowledge acquired in the school one would not work as hard as the other. After the work has been completed, the time noted, and the candidates have left the workshop, the work is then judged on the spot, not sent away to be examined by those who never saw how it was done. By this method we contend the candidates have every advantage given them. In the theory questions are embodied the manufacture of the articles used by plumbers, such as the composition of various solders, fluxes and their uses, planning and setting out house drainage and general sanitary work, bye-laws of the governing bodies relating to sanitary plumbing hydrostratics for pump work, setting out sheet lead with the greatest economy to save the pocket of the employer and the employer's customers, and many other points too numerous to mention.

In addition to this the company has instituted a scheme known as the "graded scheme," by which apprentices may acquire the necessary knowledge by degrees, and according to their requirements. A lad who has been at the trade two years can sit for the preliminary stage. After four years he sits for the intermediate stage, and on the completion of his indenture can sit for the final, upon passing which he is granted his certificate of registration. The practical tests comprise in all stages, work in pipe bending, soldering, lead burning, lead dressing and setting out, all having a direct practical bearing on the every day work of the plumber. When we view this by the side of the statement made in the *Engineering Magazine*, that "the question of wages seems to have very little bearing upon the capacity for competing," and in another magazine article, *The Review of Reviews*, that "we are being beaten because we are not so smart, not so brainy, so scientific, so capable, in short, as our rivals," we can claim that the work the Worshipful Company is engaged in must tend to remove this reproach from us. What the Worshipful Company is doing may with profit be followed by other City Companies to elevate the crafts from which they take their name.

Some may argue from my remarks that we are training a race of black-coated and white-handed plumbers, who will want to do all the overseeing and leave the practical actual work to the plumber's mate. Gentlemen, the very system we adopt will prevent this, because we insist on the practical test as well as the theoretical before we grant any man his certificate, so that when a person states he is a registered plumber you have not to treat with one who is only a paper plumber, but one who is actually a worker in lead. There are certificates for what is known as paper plumbers (I have one myself), but I candidly confess I am not a plumber. Yet there is no law to prevent my foisting myself on the public as a "certified plumber," and the general body of the public would not distinguish the difference between the certified and the registered ; but there is a difference, as I have shown you. This would not matter so much if there were not persons who advertise themselves as certified plumbers, with the direct object of misleading the public to think they were registered.

With a view of preventing such misunderstandings as I have indicated, the Worshipful Company has from time to time brought into the House of Commons a Bill known as the "Plumbers' Registration Bill," having for its object the safeguarding of the public health by enabling persons employing plumbers to select, when they desire to do so, persons who have given evidence of their qualification for plumbers' work. The Bill does not contemplate a monopoly ; it does not interfere in any way with the rights of non-registered plumbers. It, however, prohibits, and rightly so, such plumbers from representing themselves as registered. It was this Bill upon which I spoke some twelve months since, and in the words of a familiar verse I have again to tell you "the old, old story" of vested interests and factious opposition preventing a useful measure being placed upon the statute

book of this land. It was my good fortune to be in the House last June and July when the Bill came up for discussion, and I was struck with the unanimity with which the principle of the Bill was received, that is, the principle of the need for a measure to protect the public from the effects of bad plumbing. One speaker complained that no provision was made for inspecting work; another complained it would lead to that, and create a staff of officials, two opponents of the Bill not agreeing on that point. Other arguments against the Bill were used, not because the measure, as I have said, was disapproved in principle, but on account of engendered opposition on the part of vested interests. It has been said by some that the matter is one of financial profit to the Company, one speaker going so far as to say that what the Plumbers' Company care for was not the educating of the plumber, but the monies to be received in fees. Well, gentlemen, there never was a weaker argument advanced than that against any measure, but in this case it is not worth noting. But it is one that I often meet with in my connection as secretary to this Council, and therefore I will refer to it with a view of removing any misconception you may have in your minds on the subject. The Bill does not seek to alter the present arrangement with regard to the liability of the Company in this matter. At the present time the costs of the examinations are borne by the Company, these expenses including the cost of materials, fires, attendance, examiners' fees, and all other incidental expenses. Now, supposing that twelve candidates presented themselves for examination, each having to be provided with sheet lead, lead pipe, solder, and in many cases rent of workshop to be paid for, as a result of the examination, perhaps one, or maybe two, would be granted certificates of registration, which upon its being taken up by the candidate would mean the payment of 10s. 6d. on the part of an operative, and £2 2s. on the part of a master, thus working out at profit of, say, £1 1s., costs £7—not much of a money-making or fee-grasping concern, as represented by one of the speakers in the debate. Another speaker announced that the Bill would put "a ring fence round a trade." Now the Bill expressly states that no interference is to take place with the men who are not registered. If a genuine system of apprenticeship, such as existed in years gone by, could be insisted on and carried out, you would then have what the opponents to the Bill describe as a ring fence, but such a thing is not created under this Bill. The objectors to the Bill desire to see the teaching of young plumbers solely in the hands of book-learnt teachers, whilst the Company seeks to place the teaching of young plumbers in the hands of good practical experienced men, who may be at liberty to call in any scholastic aid that may be required. But all hands seem agreed, as I have already said, on the principles of the Bill, the chief opposition being the method of examination, practical *versus* theoretical.

Now I come to the question of those men who have been in the trade prior to a date named in the Bill—that is, prior to 1887. If the person who is desirous of being registered can produce satisfactory evidence that he served his time at the plumbing trade, having actually used the tools, not like many who seek to be registered because they have worked with their fathers in the front shop over the counter, these persons whilst engaged in the trade are not considered plumbers in the true sense of the word. It would be manifestly unfair to keep out such a man, who may perhaps have worked for upwards of thirty or forty years at the bench, or to make him take his stand in the examination-room by the side of a younger man who had received all the advantages of the technical schools with its higher training. Therefore, the Bill provides that these men shall, upon satisfactory proof, be registered without having to go through the examination—an arrangement at once fair and just. The Bill does not seek to in any way interfere with the questions which at times agitate the country in relation to capital and labour, the aim being purely educational, and to protect those who are capable of being registered from being confused with those who are not, viz., with what I have described as the paper plumber. I do not wish to say a word against these men, only they must not pose as practical men when they are not—that is, they must not lead the public to think they are registered. Now, having given you a brief summary of what the Bill proposes to do and what it proposes not to do, may I ask your support to a plain resolution which I shall propose, that is:—"That this meeting of public representatives of master and operative plumbers of Exeter and district desires to express its approval of the efforts of the Worshipful Company of Plumbers to elevate the craft, protect the public from bad plumbing, and to give effect to these objects by the Bill about to be promoted in the House of Commons during the forthcoming session of Parliament." I feel sure that if you give your approval to this resolution you will help the Company, the public, and the craft to place upon the statute-book that measure which is the legitimate aim and aspiration of the interests I have named.

The motion was seconded by Mr. COUNCILLOR COLE, supported by Mr. HARVEY, and carried unanimously.

The CHAIRMAN pointed out that those who wished to be worked up in the theory of plumbing could, by making an application to the principal, get a class started at the Exeter Technical College.

On the motion of Mr. KERSLAKE, seconded by Mr. STONE (Crediton), a vote of thanks was passed to the deputation from Plymouth, and the chairman was also thanked for presiding.

FLINTSHIRE.—An epidemic of diphtheria has broken out at Mostyn, Flintshire, forty cases having been recorded in fourteen days, and so far eleven deaths have occurred. The Medical Officer is not satisfied as to the cause of the outbreak, but advocates watchfulness over the milk supplies.

Duration of Immunity after Vaccination.—According to Jasiewicz, the immunity from vaccination lasts a much shorter time in infants than is generally supposed. A study of the statistics of the subject showed a proportion of 7·35 per cent. out of twenty-three children under six years of age in whom vaccination was successfully performed. The author, therefore, recommends more frequent re-vaccination in childhood, and expresses the opinion that children are also protected from other infectious diseases thereby.—From the *Journal de Clin. et Ther. de l'Enfance*, July 29th, 1897.

Institute of Sanitary Engineers

THE CHEMICAL EXAMINATION OF WATER.

By RICHARD HORTON.

AT the monthly meeting held on the 3rd inst., Mr. Richard Horton read a paper on the above subject. The chair was occupied by Mr. Dove.

Mr. HORTON said:—The variety of knowledge required of sanitary engineers is extensive, and one would perhaps think that the chemical examination of water would be best left in the hands of experienced chemists. It may, therefore be as well to say at the outset, that it is not the intention of this paper to advise the tacking of another science to one already heavily laden, but it is intended to suggest that some acquaintance with the subject is necessary to all sanitary engineers who aspire to be, as nearly as possible, up to date.

It was, until comparatively recent times, considered that the analysis of water afforded a most reliable guide as to its safety for drinking purposes, but it is now considered by some authorities that a bacteriological examination is the only test; by others, that a judgment based upon chemical analysis and bacteriological examination taken conjointly is best; whilst others affirm that the bacteriological examination is of little value unless carried out more carefully than it is at present; that it is not sufficient to know the number of bacteria in a cubic centimetre of the water, and whether they do or do not liquefy gelatine, but that it is absolutely necessary that the particular organisms present should be identified before a water can be either recommended or condemned.

The latter view of the matter seems very rational, and when the examination is required to trace the cause of an outbreak of some zymotic disease, the argument is unanswerable, but such an examination, or anything like it, is utterly impossible to the sanitary engineer who has to give, very often in a couple of days, his opinion as to the safety of a house for habitation.

In the case of London houses, it is simply necessary to ascertain that the water is not fouled in any way by insanitary arrangements; information as to the chemical purity may be had from official reports; but in country and outlying districts the water supply needs very careful consideration. When the supply is from shallow wells, the water is generally uncertain, and therefore unsafe to drink; but deep wells are by no means beyond suspicion. In my own experience, a house near Tunbridge Wells was examined, and found to be in a fairly sanitary condition, and the water affirmed by the owner to be very pure, as it was drawn from a deep well. I brought a sample back to town, and upon analysis discovered that it was unmistakeably polluted, and reported accordingly. On a second visit, the well, which was in cultivated ground, was opened for my inspection, and proved to be 60ft. deep, the source of impurity being very evident. About 20ft. of the upper part was built of loose brickwork, and every facility afforded for draining the manured ground into the well. This was rectified and the well cleaned, the water subsequently drawn from it showing on analysis a very marked difference, as I will show later.

An owner generally informs an inquirer that the well is very deep, and the experienced observer will sometimes notice the pump fixed above the ground level, with a smile of unbelief in the assertion; but it is not always safe to trust entirely our first impression as to the depth of a well. A year or two since, in North London, a well was condemned and the owner ordered to lay on water from the town supply. I managed to secure a sample of the water, which, upon analysis, proved of very good quality, and unlike what one expects from a well of 18ft. in depth, as this was supposed to be. An examination of the water made subsequently by the Public Analyst showed similar results, and the well was afterwards discovered to be 68ft. deep (363ft. above sea level), the water keeping at a constant depth of about 58ft. The Public Analyst's remarks appended to his results were as follows:—"These facts show the water to be one of high organic purity, and of far better quality than the mass of the water supplied to London. It is perfectly free from the least suspicion of contamination with sewage or surface drainage." The well was, of course, not closed.

At about the distance of half a mile above is another well, which is 374ft. above sea level, 23ft. deep, and placed under a kitchen floor. The Public Analyst's examination of the water from this well showed 25·38 grains of chlorine, as common salt, to the gallon, but rather curiously no free ammonia, and only ·071 parts per million of albuminoid ammonia, the total solids being large, 75 grains per gallon, the nitrates being in large quantity. The analyst reported:—"I am of opinion that this water consists largely of surface drainage as indicated by the large quantity of matter in solution, consisting chiefly of chlorides and nitrates. Such waters are not safe for drinking purposes."

I have mentioned the above cases to show that a fair opinion may be arrived at from a chemical analysis of water, at all events in some cases, I believe in most; there is, perhaps, some difficulty when the results of an analysis approaches the border line which lie between a safe and an unsafe indication of purity, or the reverse, but in such cases the sanitary engineer has simply to state his results, and leave the matter to experts.

There are practically two processes in use for the estimation of organic impurity in water:—(1) Frankland's process, by which the organic nitrogen and organic carbon are evolved from the combustion of the residue obtained from the evaporation to dryness of a given quantity of the water, and then measured; (2) Wanklyn's process, in which a certain proportion of the organic matter is decomposed, and the ammonia evolved (called "albuminoid ammonia") is measured.

Frankland's process is the one used, I believe, by the water companies, and by Dr. Frankland himself in his official analyses, but as it must be worked by experienced chemists, the process cannot be recommended for the use of Sanitary Engineers. Wanklyn's process, on the other hand, presents few difficulties, and its working is very simple, needing only care and properly standardised solutions, the latter being readily obtained from Messrs. Sutton, of Norwich, or their agents.

The following are usually determined by analysts in their examinations of water samples :—

Total solid matter, in grains per gallon :—Chlorine, as common salt ; nitrogen, as nitrates ; nitrites ; free, or saline, ammonia, in parts per million ; albuminoid ammonia ; poisonous metals, in grains per gallon ; and oxygen consumed in a given time, at a certain temperature.

Of these it will probably be sufficient for a sanitary engineer's purpose to estimate :—Chlorine, free ammonia, albuminoid ammonia, and to make a rough test for poisonous metals. Examinations for nitrates, and also the determination of oxygen consumed, may be undertaken with a small additional outlay for apparatus, but weighing the total solids will require the use of a fairly accurate balance.

To ascertain the amount of chlorine in a sample is a very simple matter, the following apparatus and solution being required :—

A 100 c.c. graduated measure, a white porcelain basin capable of holding about 100 c.c. a small burette and stand, a standard solution of silver nitrate, containing 4·79 grammes of silver nitrate to a litre of distilled water (one cubic centimetre of which solution is capable of precipitating one milligramme of chlorine), a little potassium chromate, and a small glass rod. The operation is as follows :—

Measure exactly 70 cubic centimetres of the water into the basin, and stir in about 20 milligrammes of potassium chromate, which will tinge the water a distinct yellow, fill up the burette with the standard solution of silver nitrate, and adjust by means of the tap, so that the surface of solution is level with the zero mark, then run the solution very gradually into the prepared water. As each drop touches the surface a dark red colouration will appear at the point of impact, which upon stirring with the rod will disappear, and the addition of silver nitrate solution is continued until the red colouration becomes permanent, the process being closely watched, and stopped when the faintest red colouration is permanent. The number of cubic centimetres used is then read off the burette, and as each cubic centimetre of the standard solution represents one milligramme of chlorine, the amount read off indicates the number of milligrammes contained in 70 cubic centimetres of the sample taken.

As it is usual to return the amount of chlorine found in grains per gallon, and a gallon of water weighs 70,000 grains, therefore 70 cubic centimetres, or 70,000 milligrammes of the water are taken, so that — parts per 70,000 may be correctly read as — grains per gallon.

The process depends upon the fact that water containing chlorine forms a white precipitate with silver nitrate, but as it would be impossible to determine the point at which all the chlorine was satisfied, potassium chromate is added, which at the critical point forms red chromate of silver with the nitrate, the silver not combining with the chromic acid of the chromate until all the chlorine is used up. The water should not be acid, as chromate of silver is dissolved by acids.

Chlorine, as common salt, exists in urine and sewage, and as a natural water, unless taken from the neighbourhood of salt springs, does not contain it, except perhaps in small quantity, the presence in a sample of a large quantity of chlorine points to pollution with animal or sewage matter ; but, on the other hand, its absence does not by itself prove the purity of the water, as contaminations may be present from a vegetable source.

The chlorine may be expressed as common salt as follows :—Taking the atomic weights of Na (sodium) as 23, and Cl (chlorine) as 35·5, NaCl (common salt) = 35·5 + 23 = 58·5, therefore :— $\frac{58{\cdot}5 \times n}{35{\cdot}5}$ = the amount of NaCl present, when n represents the amount as Cl.

(To be continued.)

General News.

HOME.

NOTICE.—On and after 31st March next the Annual Subscription to this Journal will be raised to 12s. 6d. to all NEW Subscribers. NO ADVANCE will be made to our friends whose names are entered on our Subcription list prior to that date, so long as they continue to Subscribe.

NAIRN.—A special water supply district is to be formed to supply the houses in the vicinity of the town.

MALDON.—The Town Council has resolved to oppose the Bill of the Maldon Water Supply Company, Limited.

HALIFAX.—The Town Clerk has been instructed to apply to the Local Government Board for sanction to borrow £11,200 for the purposes of a small-pox hospital.

BIRKENHEAD.—At the last monthly meeting of the Town Council a resolution was passed in favour of erecting salt-water baths at the north end of the town, to cost £13,000.

LEICESTER.—A Local Government Board inquiry has been held with respect to the application of the Council for the Board's sanction to a loan of £54,000 for the proposed new isolation hospital at Gilroes.

YEALMPTON.—The Parish Council has decided that as the Local Government Board has refused to sanction a loan for a water supply, the matter be referred back to the District Council, asking it to give the matter its immediate attention.

CHAPEL-EN-LE-FRITH. — The Guardians have decided to ask for permission to borrow £864 for the erection of a laundry at the workhouse, and to ask for the sanction of the Local Government Board to the workhouse drainage scheme.

GODALMING.—The Town Council has decided to acquire the water supply of the borough and adjoining districts from the Godalming and Frith Hill Water Company. It is estimated that the waterworks will cost upwards of £30,000.

FRIERN BARNET.—The Urban District Council has resolved to write to the London County Council that the regulations as laid down as to keeping the subsoil and surface water out of the sewers before Friern Barnet took the sewage of the asylum must be complied with.

MAIDSTONE.—The District Council has resolved to apply for an Act of Parliament for the purchase of the waterworks.

TORQUAY.—The Town Council has decided to appoint an Assistant Sanitary Inspector at a commencing salary of £100 per annum, rising to £150.

MANSFIELD WOODHOUSE.—The District Council has decided to make application to the Mansfield Corporation for a loan of £3000, to carry out works of a water supply.

THURSO.—The Burgh Commissioners have unanimously agreed to apply to the Local Authority for its sanction to erect a public slaughter-house on their own ground at the riverside.

HASTINGS.—Samples of the water are submitted monthly to Dr. Dupré, the eminent analyst, who reports that the water, which is filtered through polarite, is of great organic purity, and of the highest class.

NEWPORT.—At a special meeting of the Urban District Council the Sanitary Committee reported that it had visited the Barnhurst farm, near Wolverhampton, and inspected the filtration works there, and recommended the adoption of a similar method for Newport. After much discussion the consideration of the matter was adjourned.

CHESHIRE.—The Mayor of Chester, on the 25th ult., laid the foundation stone of an infectious diseases hospital to be erected at Sealand, about a mile from the city, at a total estimated cost of about £20,000. In Mid-Cheshire a controversy has been going on for some months between the County Council and the Local Authorities as to the provisions of isolation hospitals, but nothing has yet been done.

WATFORD.—The Urban District Council has received from Professor Attfield his quarterly report on the water supplied to Watford from the urban district mains. A sample received by him on January 17th, was clear, inodorous, and palatable, and showed that the water compared favourably with the best public supplies to our cities and large towns. In his opinion the water was of excellent quality for all drinking purposes.

BRIDLINGTON.—A Local Government Board inquiry has been held into the applications of the Urban District Council to borrow £1100 for purchase and construction of a public lavatory on Shiphill at the quay; £1100 for the purchase of land and construction of a wall to enlarge the Council's stoneyard; £1000 for the re-laying and construction of sewage outfall works on the north side of the beach; and £1000 for the making of a new street.

WORCESTER.—In consequence of a recent outbreak of diphtheria at the Cottage Homes of the Workhouse, inquiries have been made, and the result was reported to the Board of Guardians at the last fortnightly meeting. It was stated that owing to the condition of the drains at the Cottage Homes, which are of recent construction, the sewage was finding its way into the soft water tank, as there was no trap to the pipe taking the overflow from the tank to the sewer. It was further stated that sewage a yard in depth was discovered in the soft water tank. It was decided to ask the architects, Messrs. H. Rowe and Son, to meet the Cottage Homes Committee at once.

EDINBURGH.—The Public Health Committee of the Town Council has approved of the recommendation of its sub-committee for the appointment by the Corporation of a chief Sanitary Inspector under the Public Health Act.

LEITH.—The deaths registered within the burgh during the month of January numbered 102, being a decrease of three on the preceding month, and a decrease of 22 on the corresponding month last year, and showing a death-rate equal to 15·7 per 1000 of the estimated population.

KELSO.—The Commissioners of the burgh, after considering Sir Henry Littlejohn's report to the Local Government Board on the water supply of the burgh, have remitted the same back to the New Water Supply Sub-Committee to report on it, with a view to the latter being forwarded to the Local Government Board.

GRANGEMOUTH.—The scarlet fever epidemic which broke out so suddenly, and was traced to an affected farm in the district, is now reported to be abating. There have been forty-three cases notified, which are all of a very mild type. The measures taken seem to have been very effective in checking the disease, as only a few cases have been reported within the last few days.

Personal.

MR. J. TODD has been appointed Medical Officer of the Workhouse, Gateshead.

DR. WILLIAMS has been reappointed Medical Officer for the Town Council of Leominster.

DR. H. MANLEY has been appointed Medical Officer for West Bromwich for the ensuing year.

MR. F. C. YOUNG has been appointed Medical Officer for the Twyford district of Wokingham union.

MR. JAMES MORRIS, A.S.I., has been appointed Assistant Inspector of Nuisances for the borough of Eccles.

H. DONALDSON, M.R.C.S., has been appointed a Public Vaccinator for the district of Gore, New Zealand.

W. C. DAISH, M.D., has been appointed a Public Vaccinator at South Melbourne, Victoria, Australia.

MR. G. R. HARLAND has been appointed Assistant Medical Officer of the Workhouse, Gateshead.

MR. JOHN ROBERTS has been appointed Inspector of Nuisances for the urban district of Llanrwst.

MR. A. J. A. THEOBALDS has been appointed Medical Officer for the Walgrave District of Wokingham Union.

MR. H. J. BROWN has been appointed Vaccination Officer for the Streatham district of Wandsworth and Clapham Union.

H. E. BELCHER, L.R.C.P., M.R.C.S., has been appointed Medical Officer for the West Bridgford sanitary district of the Basford union.

DR. A. W. THOMAS has been reappointed Medical Officer of Health for the urban district of Swaffham, at a salary of £20 per annum.

MR. JOHN STEVENSON, of Ayr, has been appointed Burgh Surveyor and Sanitary Inspector for Girvan, in room of Mr. David Robertson.

F. A. HALLSWORTH, L.R.C.P., M.R.C.S., has been appointed Medical Officer for the Bodenham sanitary district under the Leominster union.

THE Local Government Board has sanctioned the reappointment of Dr. R. Bonstead, as Medical Officer of Health for Hexham, at a salary of £210.

THE Local Government Board has sanctioned the appointment of Dr. Shepheard as Medical Officer of Health for the urban district of North Walsham.

MR. HARRY HOLMES, of the borough engineer's office, Burton-on-Trent, has been appointed engineering assistant in the city engineer's office, Birmingham.

DR. ANNINGSON has been reappointed Medical Officer, and Mr. Master, Inspector of Nuisances for the District of Chesterton, at salaries of £60 per annum each.

THE Local Government Board has sanctioned the appointment of Mr. Herbert E. Bellamy as Chief Inspector of Nuisances for the City Council of Truro, at a salary of £100 per annum. Mr. Bellamy has been an assistant in the Health Department of the county borough of St. Helens for a period of seven years.

MR. WILLIAM SUMMONS, who had for very many years filled the office of Sanitary Inspector and Surveyor at Milford Haven, died suddenly at his residence in that town on Sunday, January 30th. Deceased, who was about sixty-eight years of age, had not enjoyed good health for some time past, but was able to attend to his duties up to the day before his death.

Sewerage Schemes.

[TO MUNICIPAL ENGINEERS AND SURVEYORS.—The Editor will be pleased to receive items for publication relating to sewerage schemes projected or inaugurated, together with explanatory diagrams or photographs. The former should be drawn and lettered in black ink.]

THE Rural District Council of Wokingham has referred the schemes dealing with Sonning drainage to a parish meeting.

THE Local Government Board has sanctioned the loan of £2437 for works of sewerage and sewage disposal at Buckfastleigh.

THE Urban District Council of Portishead is about to apply to the Local Government Board for sanction to borrow £3000 for sewage works.

THE Public Works Loan Commissioners have been asked for a loan of £36,000 to carry out the Aber Valleys sewerage scheme at Rhymney.

A LOCAL Government Board inquiry was held at Ilford on Thursday, the 3rd inst., into the application of the Urban District Council for permission to borrow £1660 for sewerage works.

THE Crieff Town Council has resolved to borrow £500 for defraying the expense of the improved drainage system in the lower part of the town.

THE Surveyor to the Dunstable Council has presented his report (with plan) on the Luton-road site for the proposed sewerage scheme by gravitation.

THE Tavistock Council has agreed to adopt a drainage scheme for the drainage of certain houses on the Whitchurch-road, and to borrow £300 to carry out the work.

THE Wendover Rural District Council has decided to petition the Thames Conservators to grant a further extension of two years before carrying out a system of drainage at Wendover.

A LOCAL Government Board inquiry has been held at Wickwar with regard to the proposal of the Rural District Council to borrow £500 for purposes of sewerage and sewage disposal for the parish.

AT a recent meeting of the Gomersal Urban District Council minutes were confirmed of a special meeting at which plans of the drainage scheme had been formally approved, and at which the clerk had been directed to apply to the Local Government Board for sanction to borrow £8000 for carrying out the work.

THE tender of Messrs. Walker and Co., of Keighley, for the sewerage of Morton, amounting to £4141 6s., has been accepted. Only a portion of the work is to be done at present, that from Morton village to Dimples, and from Morton Banks to the Marquis of Granby Inn. The amount of the tender for these sections is £2338 9s. 9d.

THE Brynmaur Urban District Council has decided to apply to the Local Government Board for sanction to borrow £2500 for the purchase of the Rhonos Farm, and costs to the Council, attending sale andconveyance of the farm together with the expense of improving the works needed for distributing more effectually the sewage.

A SPECIAL meeting of the Shaftesbury Town Council was held recently to receive a report from the Borough Surveyor with reference to the drainage at Ivy Cross. Mr. W. Genge reported that the drain which was laid down about a year ago to connect the houses at Ivy Cross with the main drainage of the town in Bleke-street was choked. This was caused by the improper manner in which the pipes had been laid, which for eighty-seven yards after leaving the top of Dark-lane going in the direction of the town had a reverse fall. The surveyor was instructed to take up the pipes and have them relaid in a proper manner, and give a fall of 2in. in 10ft.

MR. C. B. WITTS, C.E., of Cheltenham, met the Sewerage Committee of Burford on Tuesday, the 1st inst., concerning the proposed scheme of disposing of the sewage matter of the town of Burford. Objections having been made by the District Council to the plans which Mr. Witts had submitted, it was decided that he should prepare another scheme with a view to meet any opposition from the Local Government Board.

IN consequence of the repeated complaints received by the Ilkeston Town Council from the people of Hallam Fields as to an alleged nuisance arising from the sewage farm at that place, the Town Council paid a special visit to the farm on Wednesday, the 2nd inst., and received a deputation appointed by a recent meeting of the inhabitants. The state of things was found to largely confirm the previous reports of the Health Committee—that no nuisance existed.

Mr. W. J. DIBDIN has just presented a further report to members of the Leeds Streets and Sewerage Committee in reference to the experimental purification of the sewage of Leeds by the bacteriological method. The committee, on Tuesday, the 1st inst., drove to the works at Knostrop, and there met Mr. Dibdin, who explained the practical working of his system. The operations comprise first, the preliminary breaking down of complex organic bodies and the liquefying of the solids suspended in the sewage, this being effected by the agency of micro-organisms in a bacteria bed filled with coarse coke; and, secondly, the final oxidation, coupled with a complete removal of the remaining suspended matters, by similar action in a bed of finer grain. If it is found possible to extend the system, a considerable outlay in the purchase of land and the erection of sewerage works will be saved the ratepayers of Leeds.

A NUMBER of representatives of local bodies visited Pleasley on Wednesday, the 2nd inst., to inspect works which have just been completed at Shirebrook and Pleasley, in the Blackwell Rural District, at a cost of about £6000. At Shirebrook, where the inspection began, the series of tanks is in a rectangular form. A number of chambers are built of stone and concrete, the first chamber, which receives the sewage after it has been subjected to the precipitating action of chemicals, being about twice the size of the others. The greatest proportion of solid matter is precipitated in the first chamber, the precipitation becoming less in quantity as it passes gently through the other chambers, until at the bottom of the last there is very little solid matter to be found at all. The clearness of the water at the effluent, of which several samples were taken, showed that the treatment of the sewage had been adequate and successful. The system is that invented by Mr. Cosham, of Newark. The party next proceeded to Pleasley, where works on the same principle had been constructed, excepting that, instead of rectangular, the chambers are in a circular form. The plans of the works were prepared by Mr. Walker, engineer, of Nottingham, and the contracts have been satisfactorily carried out by Messrs. Lane and Son, of Skegby.

AT the last monthly meeting of the Ludlow Town Council the present system of sewage disposal was reported to be very bad and thoroughly inefficient. The tanks were objectionable, and the effluent passed into the river chemically untreated in any way. The system constituted a grave violation of the Rivers Pollution Act. The Sanitary Committee reported that the time had arrived when the sewage disposal scheme should be proceeded with. The cost will probably be between £7000 and £8000.

AMONG the large undertakings of the Public Works Department of Australia is the Sydney sewerage system, which, in its present complete form, is of comparatively recent date, the works having been only commenced in 1880. Briefly described, the works consists of a main northern outfall sewer, which collects the sewage of the portion of Sydney and suburbs which naturally drains into Port Jackson, and discharges into the Pacific Ocean at a point about five miles to the south of Sydney Heads. The sewage of the southern district is collected into a separate system and conveyed to a sewage farm on the shores of Botany Bay. The scheme also comprises a system for the western suburbs, which also discharges on to the sewage farm at Botany. In addition to the extensive reticulation works in connection with the main scheme, numerous storm-water drains have been constructed where foul and insanitary creeks formerly existed. The amount expended on these works up to June 30th, 1896 was £1,920,008, including a small expenditure on country sewerage. The effect which the construction of the sewers has had upon the health of Sydney has been most marked.

WITH reference to a paragraph appearing under this heading in our issue of January 21st, dealing with the working of the Cleckheaton sewerage works, a correspondent writes:—"I shall be obliged if you will kindly give the facts of the case, which are as follows:—The district of the Cleckheaton District Council embraces the hamlets of Scholes and Oakenshaw, in addition to Cleckheaton proper, and in the year 1889 the late Local Board carried out a scheme of sewerage and sewage disposal for the Scholes portion of their district, which works were designed and carried out by Mr. Woodhead, Surveyor of Bradford, and during some portion of last year (through the alleged negligence on the part of some person who had the management of this sewage farm) the Rivers Board Inspector complained of the impure state of the effluent, and the Council have now decided to call in Mr. Woodhead (as the designer of the scheme) to advise them as to remedying the complaint. I may say that the new sewerage scheme, which is being carried out for the township of Cleckheaton proper has been designed by Mr. J. C. Haller, A.M.I.C.E., on the latest and most approved system, and is giving entire satisfaction to all parties concerned. The whole of the Cleckheaton sewers are connected into the Liversedge District Council's main trunk sewer, and the sewage is being treated at the Liversedge sewage disposal works by that Authority under contract with the Cleckheaton Council."

A PUBLIC meeting was held in Bourne Hall, Douglas, on Wednesday night, the 2nd inst., called with the intention of overthrowing the scheme of drainage which the Corporation has embarked upon, in favour of drainage by natural gravitation. The scheme in progress embraces what are known as Adam's automatic lifts, to be used for lifting the sewerage from a lower to a higher level, and prevent back-flowing in the seaward portion of the town. A resolution was carried approving the substitution of the scheme of gravitation, and a deputation was appointed to give evidence before the Tynwald Court Committee in favour of this scheme, which has been once adopted by the Town Commissioners, the estimated cost being £30,000. It was stated that the present scheme would not be completed under £80,000.

Lighting.

THE directors of the Rothbury Gas Company have decided to reduce the price of gas from 5s. to 4s. 7d. per thousand feet.

THE Law and Finance Committee of Greenock Town Council has under consideration the question of introducing electric light into the town.

A LOCAL Government Board inquiry has been held at Cardiff in connection with an application for sanction to borrow £29,500 for the purposes of electric lighting.

THE City Engineer for Newcastle has been instructed to furnish a report as to the amount of power capable of being produced from the waste energy of the Byker refuse destructor.

THE Local Government Board has intimated to the Dublin Corporation that it will grant to that body a loan of £20,000 to be applied in repairing and completing the electric lighting system of the city.

A LOCAL Government Board inquiry has been held at Walsall with reference to an application by the Town Council for permission to borrow £700 for increase of the engine-room power of the electric lighting plant.

A COURT of Inquiry was held at Broughty Ferry recently regarding an application to the Secretary for Scotland for a Provisional Order to enable the Burgh Commissioners to ask additional borrowing powers for the extension of the gas works.

THROUGH the efforts of the Currie Lighting Committee, a great public improvement has just been carried out by the extension of the Edinburgh gas to Currie. The work of laying the gas main has been in progress during the past two months. An arrangement has been made with the Edinburgh Gas Corporation for the sale of the gas in bulk to the Local Committee, who undertake the management and distribution.

THE Hampstead Vestry has decided to apply for a loan of £40,000 from the London County Council in order to pay for some very extensive plant for electric lighting it has just added to the central station in Finchley-road. The St. Pancras Vestry is at work extending its installation to meet that of Hampstead, at Chalk Farm, and as a result one straight road, reaching almost from Oxford-street to Hampstead Heath, will be illuminated by the electric arc light.

A SUCCESSFUL installation of electric light has lately been completed in Treeton by Messrs. J. Dewhurst and Son, Limited, of Sheffield. The contract for the work was £600, but owing to the requirements of the Board of Trade this estimate has been exceeded by £140. It has been resolved to obtain the sanction of the County Council and Local Government Board to this sum, and to raise the sum of £210 for lighting purposes under the Lighting and Watching Act, 1833, during the ensuing year.

THE Electric Lighting Committee of the Shoreditch Vestry recommends, that owing to the success of the Vestry's efforts in the combined scheme of the generation of electricity from the steam supplied by the dust destructor, the Vestry reduce the charge for electricity from 6d. per unit for the first two hours, and 4d. per unit for the surplus, to 6d. per unit for the first hour and a-half, and 2d. per unit afterwards. The Vestry has resolved to defer the Committee's recommendations till after the financial year's statement in March.

AT a recent meeting of the Southgate Urban District Council, a letter was received from the solicitors of the Tottenham and Edmonton Gas Company enclosing a copy of a clause the company were willing to insert in the Bill as to illuminating power and purity of gas. The Council eventually decided to petition against the Company's Bill. It was mentioned that the Company had lighting powers over less than half the district, and that the powers sought to supply electric light within the district would consequently not apply to the larger half thereof now lighted by the Colney Hatch Gas Company.

MESSRS. YOUNG AND MARTEN'S DINNER.

THE fourth annual dinner of the heads of staff of the firm of Young and Marten, Caledonian Works, Stratford, took place at the Holborn Restaurant on Saturday, 29th ult., with Mr. H. H. Marten, proprietor, in the chair, and Mr. E. Montague Edwards, general manager, in the vice-chair, Mr. Frank Marten and Mr. Ernest Marten were also present.

The first toast was that of "The Queen," which was submitted by the Chairman and duly honoured.

Mr. E. M. EDWARDS, vice-chairman, stated, in proposing the health of "The Proprietor of the Business, and Success to the Firm of Young and Marten," that it was the toast of the evening, and he regarded it as an honour that he was privileged to propose it. He spoke of the achieve-

ments of the firm, and the name they had gained through supplying goods of sterling value at a nominal figure, and with promptitude and dispatch. They had gained a position in the building world which was envied by many. The future success of the firm, he felt, was assured; the catalogue just completed and now being distributed amongst the firm's *clientèle* he considered, without speaking egotistically, was one of the finest and most comprehensive that had ever been attempted; eulogies from all parts were flowing in to headquarters, and the trade Press had spoken most encouragingly of it. The new stores, for which the contract had just been accepted, would cover a stocking area of four times the firm's present capacity, and would enable it to hold a large increased stock, a very essential item in ensuring one of the points always fought for by the firm, that was promptitude. The shipping department, though yet in its infancy, began to grow, and if properly nurtured would stand on its own merits, as every department of the business did.

The CHAIRMAN, in response, said: I have once again to thank you, Mr. Edwards, for the kind remarks you have made in proposing my health, and also for the eulogistic expressions you have used in reference to the firm of Young and Marten, of which I have the honour to be the proprietor. I think these annual dinners are a splendid institution, from two or three points of view. There is the social and commercial aspect, and, if I might say so, the expedient point of view. I think it is expedient and desirable that we should meet here once a year, not only to enjoy a social evening, but also to interchange ideas with regard to the progress of the business. But with regard to the commercial aspect, last year I expressed the hope that 1897 would be a record year, and I am glad to say the volume of trade done justifies that hope, as we had a considerable increase in our turnover. There is one feature of 1897 that will stamp it for ever in the annals and history of the firm, and that is the production of the new catalogue. I propose to speak of this later on, so I will content myself now by saying the work will place us in the foremost rank of the trade as builders' merchants. I have no doubt that 1898 will be considerably benefited by it, and as the outlook for this year is more promising than last, I feel sure, with your assistance, gentlemen, we shall have at our next meeting successful issues to relate. Now, with regard to the social question, I am only too pleased to preside here to-night, and spend a pleasant evening with you. I am glad to see the old faces, and welcome the two or three fresh ones. I am sure if they follow in the footsteps of you gentlemen that have been in the employ of the firm for many years, the prosperity of the future business of Young and Marten is assured.

The CHAIRMAN, in submitting the toast of "General Manager and Staff," said: I have now to propose what I consider is the toast of the evening, that is, the health of your worthy vice-chairman and manager, Mr. Edwards, and the staff of Young and Marten. Gentlemen, each year as it passes away adds, if possible, to the pleasure I feel in proposing this toast, as each year helps to cement more and more the feeling o unity and loyalty that exists between the staff and myself. With regard to our worthy vice-chairman, he needs no eulogy from me, as his well-known ability and indomitable energy speak for themselves, but I cannot allow this evening to pass over without paying him a tribute of praise with regard to our new catalogue, a commendation in which I am sure you will all join; he has worked incessantly in the production of the book for four or five years, and the result must be not only gratifying to him, but to all you gentlemen concerned who have assisted in its production. With regard to yourselves, gentlemen, how can I fail to be proud of such a staff? No general in the Army could possibly have a more energetic and loyal body of men than I see around me this evening. I thank you most heartily for all your services; and I rejoice to think the same unity of spirit, respect, and esteem still exist between us.

The VICE-CHAIRMAN, in replying, said that he appreciated, on his own behalf, the kind words of encouragement which had fallen from the lips of Mr. Marten. He felt also that the staff would in a like sense appreciate them. Mr. Marten was at all times liberal in the treatment of difficulties. With regard to the catalogue, the speaker stated that although he bore the full onus of its compilation and completion, nevertheless there were those present who had materially assisted him, and to them credit was due; therefore the honours were distributed, although not specifically named.

Mr. FRANK MARTEN proposed the health of the "Dinner Committee." Mr. S. A. STOOKE, in responding, said the greater portion of the work and arrangements had fallen upon Mr. R. Letby, to whom great praise was due.

A capital musical programme was arranged by the Musical Committee, which was much appreciated.

Notes and Queries.

[Subscribers have the privilege of obtaining advice in this column on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed to THE EDITOR, "Notes and Queries," THE SANITARY RECORD, 5, Fetter-lane, London, E.C.]

NOTE.—If an answer be required immediately, a stamped addressed envelope must be enclosed, when we will endeavour to furnish a copy of the answer by post, as owing to the large number of queries received we cannot guarantee the insertion of a reply in the succeeding issue.

959.—MODEL BYE-LAWS: NECESSITY FOR ADOPTION OF.—"G. F. C." writes:—"My Rural District Council will next week decide whether to adopt the Model Bye-laws as to New Streets and Buildings. After over twelve months' discussion, we seem likely to lose them. As I shall be called upon to support the proposition for new bye-laws, I shall be extremely glad if you could give me information by way of replies to the following queries:—(1) Are these bye-laws being generally adopted by Rural District Councils? (2) If adopted, are they proving a success? (3) Are the bye-laws likely to deter people from building new cottages in rural districts? (4) Does the term new building apply to improvements in old houses? (5) Or does it affect the erection of additional privies where, say, only one formerly existed for a row of four cottages? (6) Do you approve of them?"

Answer.—(1) Bye-laws as to New Streets and Buildings are adopted by most of the Urban and Rural Sanitary Authorities in the kingdom, the exception being in the case of retrograde Authorities who have yet to learn that they are responsible for the sanitary administration of their district, and to see that new dwellings are

not erected which contravene the rules of sanitary construction of dwelling-houses. (2) Yes. In securing more healthy homes, and ensuring that the health of the occupants is a prior consideration to the monetary interests of the speculative builder. (3) No. This is a "bogey"—if we may be pardoned for using the term—which is put forward in every district when a Sanitary Authority proposes to adopt the Bye-laws as to New Buildings, and is created by the speculative builder or his friends. We have never known building bye-laws deter people from building. We cannot advert too strongly on the importance of Sanitary Authorities being impressed with the fact that their duty is to protect the health of the people, and not to protect the pockets of speculators, who are too often regardless of the sanitary condition of the buildings they erect when not officially supervised. (4) Very rarely. (5) The erection of privies under such circumstances would have to be in accordance with the provisions of the New Bye-laws as to Construction, &c. (6) Most certainly. We hope the day is not far distant when building bye-laws will be compulsory in every district.

---

960. Removal of House Refuse from Premises: Neglect of Local Authority: Nuisance from Fowl Keeping.—"E. J." writes:—"(1) A notice has been served on a Sanitary Inspector to cause ashpits to be emptied. Within what time is he bound to have the work done? Please state section of the Act. (2) Would it be considered a nuisance to keep, say, fifteen or twenty fowls within 16ft. or 18ft. from a dwelling-house to the fowl-pen, and to throw vegetables, bones, meat, raw and cooked, into the fowl-yard, which is 25ft. or 30ft. from the dwelling-house? Sparrows and starlings collect in scores in the yard after the meat. Sometimes very offensive smells come from the yard."

Answer.—(1) It is not stated whether the Local Authority have undertaken or contracted for the removal of house refuse. Providing that they have undertaken the removal of such refuse, and after notice in writing from the occupier of any house within their district to remove the contents of any ashpit, the Authority fail without reasonable excuse to carry out the work within seven days, they will be liable to a penalty of 5s. per day for each day in default. See Sec. 43 Public Health Act, 1875. Proceedings for the recovery of the penalty would have to be instituted under Sec. 251 of the Act. (2) If the manner in which the fowls are kept is such as to constitute the premises a nuisance, or so as to be injurious to health, as defined by Sec. 91, Sub-sec. 1 of the Public Health Act, 1875, information may be given to the Local Authority, as provided by Sec. 93, upon the receipt of which information the Local Authority, if satisfied of the existence of a nuisance, may serve a notice under Sec. 94 on the person by whose act, default, or sufferance the nuisance arises, or continues requiring him to abate the nuisance, and on his default they may make complaint to a justice requiring him to appear before a court of summary jurisdiction, which court may make an order dealing with the nuisance. We are unable with the information before us to express an opinion as to whether the keeping of the fowls will constitute a nuisance. Our correspondent should lay a complaint to the Local Authority, when they would no doubt institute proceedings against the person in default if necessary.

— —

961.—Ventilation and Cubic Space: Calculation for.—"J. G. S." writes:—"A room 9ft. high, 20ft. long, and 10ft. broad contains six persons. The ventilating inlets, four in number, have a total area of one square foot. With what velocity per minute will the air have to enter through the inlets to supply 3000 cubic feet per head per hour? Would the conditions given be satisfactory for a dormitory or sleeping room?"

Answer.—A total quantity of 18,000 cubic feet of air would be required to enter the room per hour in order to supply each of the six persons with 3000 cubic feet. As this amount would have to pass through an area of one square foot, the velocity of the air in feet per minute will be $\frac{18{,}000}{1 \times 60} = 300$ft.

To determine whether the conditions given would be satisfactory for a dormitory or sleeping room, it will first be necessary to obtain the cubic capacity of the room and divide this by the number of persons occupying the room, afterwards comparing the result with the figures of cubic space usually allowed to be necessary.

9ft. × 20ft. × 10ft. = 1800 cubic feet, and $\frac{1800}{6} =$ 300 cubic feet of space per head.

Theoretically 1000 cubic feet of space is necessary per head, the air being changed three times per hour, so that the CO_2 may be kept below the limit of ·06 per cent., but 300 cubic feet is the amount allowed in common lodging houses. To keep the CO_2 below the limit of ·06 per cent. in this case the air of the room would have to be changed ten times per hour $\left(\frac{18{,}000}{1800}\right)$, which could not be done without a serious draught to the occupants of the room. It would appear from this that the conditions of ventilation and space available are not satisfactory for the occupation of the room by six persons.

962.—Storm-water Sewer: Power to Lay through Private Lands.—"L. F." writes:—"We are carrying out certain private street works on default of the owners,

ANTISEPTIC

DISINFECTANT. DEODORANT.

INODOROUS DISINFECTION.

Absolutely Non-Poisonous, Non-Corrosive, Non-Volatile, and does not Stain.

See published Bacteriological Report by Dr. E. KLEIN, St. Bartholomew's Hospital, London.

CHINOSOL SANITARY TABLETS are the most convenient, most effective, and most economic for the immediate production of Disinfecting Fluids. **12 Tablets**, packed in one tin to carry in waistcoat pocket, price **2s.** One Tablet in warm or cold water produces in **less than one minute**:—

3 Quarts of a strong Deodorant and Disinfectant, sufficient to spray one infected room of 1000 cubic feet; or

3 Gallons of a strong Disinfectant for flushing drains, walls, floors, &c.

Literature (Dr. Klein's Report) and Samples free to the Profession.

B. KUHN, 36, ST. MARY-AT-HILL, LONDON.

Telegraphic Address: "CARMINES, LONDON. Telephone: Avenue 5976.

of which the laying of surface-water sewers is part. There is one street which, owing to inadequate fall, I cannot connect to the other, but I could drain it into a watercourse if I could get permission to take the sewer through a small private garden which lies between the street and the watercourse. Can you inform me if the Council can compel the owner to allow it, whether he consents or not, and also state whether we should pay a small quit rent? I believe quit rents for sewers in rural districts are not allowed."

Answer.—It is provided by Sec. 16 of the Public Health Act, 1875, that any Local Authority may carry any sewer through, across, or under any road, street, &c., and after giving reasonable notice in writing to the owner or occupier (if on the report of the surveyor it appears necessary) into, through, or under any lands whatsoever, within their district. Providing, therefore, the surveyor reports to his Authority the necessity of passing through the land named by our correspondent, and that reasonable notice is given to the owner or occupier, we are of opinion that they may carry out the work proposed. The Local Authority may be required to compensate the owner and occupier for any damages sustained, but they cannot be required to pay any way-leave rent. Attention may also be directed to the provisions of Sec. 67 of the Highway Act, 1835, which enact that "the surveyor shall have power to make, scour, cleanse, and keep open all ditches, gutters, drains, or watercourses, and also to make and lay such trenches, tunnels, plats, or bridges, as he shall deem necessary *in and through any lands adjoining or lying near to any highway*, upon paying the owner or occupier of such lands or grounds, provided they are not waste or common, for the damages which he shall sustain thereby, to be settled and paid in such manner as the damages for setting materials in enclosed lands or grounds are herein directed to be settled and paid."

963.—SANITARY CONVENIENCES USED IN COMMON: PROCEDURE IN CASE OF DEFAULT. — "Inspector" writes:—"This is an urban district, wherein bye-laws are in force requiring occupiers to clean out their own ashpits. It is customary for farmers to clean out and remove the ashpit refuse, each occupier paying from 6d. to 1s. each. In case of a joint ashpit used in common by several occupiers, and one of the occupiers refuses to pay his proportion, could any occupier get the ashpit emptied, pay for those who refused, and successfully sue the joint occupiers for payment of their share of cost of removal of ashpit refuse?"

Answer.—Unless it can be shown that there was an agreement or arrangement on the part of all the occupiers to pay their respective shares for work done on the order of one of the parties, we are of opinion that the expenses incurred cannot be recovered. In such cases the Sanitary Inspector may render effective assistance by serving the statutory notice to cleanse the ashpit upon the person or persons who are in the practice of refusing to pay their proportionate expenses, and in case of default the Local Authority should institute legal proceedings against them as representing the joint occupiers. If Part 3 of the Public Health Acts Amendment Act, 1890, has been adopted in the district, the Sanitary Authority, in addition to the powers contained in the bye-laws, may, under Sec. 21, Sub-sec. 2, proceed against such of the persons having the use of the sanitary convenience in common as may be in default for permitting the sanitary convenience to be in such a state or condition as to be a nuisance or annoyance to any inhabitant of the district for want of the proper cleansing thereof. The term "sanitary convenience," it may be noted, includes, as defined by Sec. 11, Sub-sec. 3, "ashpits."

Contracts Open.

The dates given below are the latest up to which tenders can be received.

BIRKENHEAD.—February 14th.—Removal of Night-soil, &c.—Chief Inspector of Nuisances, Town Hall, Hamilton-square.

LONDON, W.C.—February 15th.—Sewers, &c.—Mr. Chas. Mason, C.E., surveyor to the Vestry of St. Martin-in-the-Fields, Westminster.

EDINBURGH.—February 16th.—Sewer.—The Burgh Engineer, 1, Parliament-square.

HAM (SURREY).—February 16th.—Sewerage Works.—Colonel Seddon, engineer, 27, Bow-lane, London, E.C.

HOVE (SUSSEX).—February 16th.—Drain Pipes, &c.—Mr. H. H. Scott, Town Hall, Hove.

KING'S NORTON (BIRMINGHAM).—February 16th.—Sewer, &c.—Mr. A. W. Cross, C.E., engineer and surveyor, 23, Valentine-road, King's Heath.

NEWBOLD VERDON (NEAR MARKET BOSWORTH).—February 16th.—Drain.—Mr. W. M. Sykes, surveyor, Park-street, Market Bosworth.

SNEINTON (NOTTS).—February 16th.—Sewers, &c.—Messrs. W. and R. and F. Booker, Short-hill, Hollow-stone, Nottingham.

CHEADLE (STAFFS).—February 16th.—Sewer, &c.—Mr. F. T. Inskip, Surveyor, Brook House, Cheadle.

TIPPERARY.—February 14th.—Sanitary Works.—Mr. Joseph Gubbins, clerk, Workhouse, Tipperary.

BURNLEY. — February 16th. — Mr. S. Edmondson, district surveyor, 18, Nicholas-street, Burnley.

UXBRIDGE. — February 18th. — Sewers.—Mr. John Anstie, C.E., Engineer, 17, Victoria-street, Westminster.

LUTTERWORTH.—February 19th.—Sewer.—Mr. J. C. Coates, Surveyor to the Council, Bitteswell, near Lutterworth.

Non-Poisonous. TRADE CAMPHYLENE MARK *Effective.*

FLEMING'S DISINFECTANTS

CHEAPEST AND BEST, SOLID, LIQUID, AND POWDER FORMS.

Fleming's Non-Corrosive, Stainless Camphylene Cream is unequalled for use in Hotels, Clubs, Public Conveniences, for Flushing Drains, Sewers, &c. &c. Supplied to a large number of Corporations, County Councils and other bodies throughout the United Kingdom.—Send for Samples and Quotations—

FLEMING'S OIL AND CHEMICAL CO., LTD.,

101, LEADENHALL STREET, LONDON, E.C.

Agents Wanted where not already represented.

Vacancies.

CLERK OF WORKS (DENBIGH, February 19th).—For the North Wales Counties Lunatic Asylum. Salary £2 10s. per week. Mr. William Barker, clerk to the Visitors, North Wales CountiesLunatic Asylum, Denbigh.

CLERK OF WORKS (BALLYSHANNON, February 18th.)—For the Guardians of Ballyshannon Union. Mr. James Perry, M.E., M.I.C.E., county surveyor, Galway.

CLERK of WORKS (LONDON, N., February 15th.)—For the Tottenham Urban District Council. Salary £2 10 per week. Mr. P. E. Murphy, engineer to the Council, 712, High-road, Tottenham, N.

CLERK OF WORKS, (LONDON, E.C., February 17th.)—For the Vestry of Shoreditch. Salary £3 3s. per week. Mr. H. Mansfield Robinson, clerk, Town Hall, Old-street, E.

ENGINEER (February 14th).—For the Brook Fever Hospital, Shooter's Hill, Kent. Wages 60s. per week, with board, lodging, washing, and uniform. Forms of application can be obtained at the Chief Office of the Metropolitan Asylums Board, Norfolk House, Norfolk-street, Strand, W.C.

ELECTRICAL ENGINEER (BIRKENHEAD, February 18th.)—For the Corporation. Salary £300 per annum. Mr. Alfred Gill, town clerk, Town Hall, Birkenhead.

INSPECTOR OF NUISANCES (HEREFORD, February 19th.)—For the Corporation of the city of Hereford. Salary £150 per annum. Mr. Joseph Carless, town clerk, Hereford.

SANITARY INSPECTOR (LONDON, S.E., February 15th).—For the Vestry of St. Mary, Newington, London. The salary will commence at £110 per annum, with an annual increment of £5 to a maximum of £150. Application forms supplied by Mr. L. J. Dunham, vestry clerk, Vestry Hall, Walworth, S.E.

COMPETITIONS.

WINCHESTER, February 28th.—Public Baths.—Full particulars, with plan of site, to be obtained on deposit of £1 1s. on application to the City Surveyor, Guildhall, Winchester, which will be returned on receipt of a *bonâ fide* set of plans. Premiums of £25 and £15 will be awarded for the designs adjudged by the Council of sufficient merit, and placed first and second in order respectively. Drawing and detailed estimate to be deposited at the office of Mr. Walter Bailey, town clerk, Guildhall, Winchester.

To Surveyors, Sanitary Inspectors, &c.—First-class Cycles at reasonable prices. Don't place your orders elsewhere until you have seen our post-free catalogue.—MELROSE CYCLE COMPANY, Coventry.

THE DRAINAGE OF VILLAGES.

BY

WILLIAM SPINKS, Assoc. M. Inst. C.E.,

Member of the Incorporated Association of Municipal and County Engineers; Member of Sanitary Institute Lecturer on Sanitary Engineering—Yorkshire College—Victoria University; President of Sanitary Engineering Section of the British Institute of Public Health, 1895.

SYNOPSIS OF CONTENTS.

PART I.—Statutory Powers—Pollution of Streams—In case of Failure to Provide Schemes—Existing Sewers—Present Means of Disposal—Composition of Sewage—Self-purifying Power of Rivers.

PART II.—Areas of District to be Sewered—Power to enter Private Lands—Works without District—Special Drainage Districts—Power to Agree with neighbouring Authority to take and deal with Sewage—Joint Sewerage Boards—Rainfall—The Geological Character of the District—Present and Prospective Number of Inhabitants—Supply of Water—Sanitary Appliances—Position of Outfall Works—Power to Purchase Lands—Borrowing Powers.

PART III.—Requirements of a Sewerage System—Depths—Gradients—Lines—Sewers and their Jointing—Manholes—Flushing—Ventilation.

PART IV.—Sewage Disposal—Purification through Land—Tanks—Sludge—Filtration.

The SANITARY PUBLISHING COMPANY, LTD., 5, Fetter Lane, LONDON, E.C.

Price 2s. 6d.; by Post, 2s. 9d.

A HEALTHY HOME.

By FRANCIS VACHER, F.R.C.S., M.R.C.P., M.O.H., Cheshire.

CONTENTS.

CHAPTER I.—**Introductory:**—Health of the Individual and Family—How shall they be Housed Wholesomely?

CHAPTER II.—**Site. Soil. Aspect:**—Desiderata as regards Site—Constituents of Soil—Ground Water—Rainfall—Diseases connected with Ground Water.

CHAPTER III.—**Building Materials.**

CHAPTER IV.—**Construction:**—Foundation—Walls—Damp Course—Damp-proof Coating—Thickness of Walls—Size of Floor Joists—Drain Pipes and Gutters—Height of Chimneys.

CHAPTER V.—**Design and General Arrangements.**

CHAPTER VI.—**Warming: Lighting and Ventilation.**

CHAPTER VII.—**Hot and Cold Water:**—Source of Supply—Pollution in Transit—Cisterns—Filtering—Service Pipes.

CHAPTER VIII.—**Sanitary Requisites:**—Drainage—House Drains—Drain Testing—Disconnecting from Sewers—Soil Pipe—Closets—Baths—Sinks—Grease and Gulley Traps.

CHAPTER IX.—**Decoration and Furniture.**

CHAPTER X.—**Stables, Cowsheds, &c.:**—Lighting and Ventilation—Drainage—Space required for each Cow.

CHAPTER XI.—**House Cleaning.**

CHAPTER XII.—**Obligations of Householder and Sanitary Authority:**—Right of Drainage into Public Sewers—Examination of Drains—Removal of Filth—Abatement of Nuisances.

THE SANITARY INSTITUTE.—LECTURES AND DEMONSTRATIONS FOR SANITARY OFFICERS.

The Twenty-fifth Course of Lectures will be held at the Parkes Museum, Margaret-street, W., on Mondays and Thursdays, commencing February 21st.

The Course includes, in addition to the Lectures, a number of Practical Demonstrations and Inspections at places illustrative of Sanitary Practice and Administration.

Full Particulars can be obtained at the offices of the Institute, Margaret-street, W.

CITY OF HEREFORD. — APPOINTMENT OF INSPECTOR OF NUISANCES.

The Corporation of the City of Hereford require, as from the 25th March next, an INSPECTOR of NUISANCES (who must possess the Certificate of the Sanitary Institute), at a salary of £150 per annum.

Candidates must not exceed 35 years of age, and should make their application by letter addressed to the undersigned, and endorsed "Inspector of Nuisances." Each application should be accompanied by not less than three testimonials, and should be sent in on or before Saturday, the 19th instant.

The duties incident to the office are those prescribed by the order of the Local Government Board, and such others as the Sanitary Committee may from time to time require to be performed.

Canvassing any of the members of the Council will disqualify the candidate so doing.

The candidate elected will be required to devote the whole of his time to the performance of the duties of the office.

JOSEPH CARLESS,
Town Clerk.

Town Clerk's Office, Hereford,
3rd February, 1898.

SANITARY INSTITUTE EXAMINATIONS.

TUITION BY CORRESPONDENCE.

An Engineer and Surveyor (Mem. San. Inst.), Certificated Surveyor and Inspector, prepares students for these Exams. by Correspondence through the post.

Fees strictly moderate. Cramming studiously avoided.

The course of tuition is arranged so as not only to qualify the student for passing the exams., but what is of equal importance, viz., that he may become a thoroughly efficient Inspector.

On successfully passing the exams., all possible assistance and advice is given to help forward intending candidates for public offices.

Many of my old pupils are now filling positions with salaries of over £120 a year.

For terms, &c., address "C. E.," care SANITARY RECORD, 5. Fetter-lane, London, E.C.

HOUSE DRAINAGE DIAGRAMS.

THE

Sanitary Record,

FEBRUARY 18, 1898.

Notes.

ON the opening of Parliament sanitarians scan with interest the list of measures that bear on those subjects with which they are concerned. The list this year is not a great one, but it includes several of considerable importance. First on the list comes the promised Local Government Bill for Ireland, from which, apart from political considerations, great things are expected. Then a foremost place in the Government programme is accorded to the "measure for facilitating the creation of municipalities in the administrative county of London." A Bill for the Amendment of the Vaccination Law is also promised for this session; following, it is to be supposed, on the lines of the recommendations of the Royal Commission. These are to be the leading measures. A number of others are promised, "should time permit;" but with a weighty programme like that which the Government have in hand, the prospects of these are not very bright. The list of minor measures includes a Bill for the Prevention of the Adulteration of Drugs and Food. What the chances are of the ill-fated Plumbers' Registration Bill it would be unwise in the meantime to attempt to predict. We have also to note Mr. Chaplin's statement that the report of the Tuberculosis Commission is at present under consideration, and may be looked for shortly.

THE Queen's Speech makes sympathetic reference to the recurrence of the plague in Western India, the alarming ravages of which are causing considerable anxiety. The death-rate is steadily rising. According to a Reuter's telegram of 10th inst., the mortality returns showed 1113 deaths from plague in Bombay during the preceding week, or an increase of 20 per cent. on the returns for the previous week. The total death-rate was 129 21 per 1000 of the inhabitants. The plague is also spreading alarmingly in the dominions of the Nizam of Hyderabad. In the Queen's Speech it is stated that the mortality is less alarming than it was at this time last year, though sufficiently so to give those in power an anxious time. No effort will be spared by the Government in the endeavour both to limit the extent of the disease and to mitigate its effects.

INFLUENZA has evidently come to stay. Every winter it lays its indiscriminating hand on the rich and the poor, the humble and the illustrious, alike. Truly it knows no distinction of persons. This year it has been particularly severe, especially in the metropolis and the southern counties, and many eminent victims have been claimed by the scourge. In London during the last week of January the number of deaths from influenza was eighty-eight, the highest number recorded in any week since March, 1895. The weather has been open and mild to an extraordinary degree, but that has not aided us in warding off the attacks of this insidious disease. Perhaps, indeed, the unseasonableness of the climatic conditions this winter may have had something to do with the prevalence of the malady. We hear that in Paris the doctors, in their anxiety for the public health and to eliminate every possible cause of sickness, have presented a petition to the Prefect of Police to suppress the queue outside the theatre doors; for they believe, and no doubt rightly, that there is no more fruitful cause of cold and influenza and all their attendant ills. To stand patiently waiting outside a theatre door in a cold wet evening is certainly laying one's self open to the risk of catching one's death of cold, but the practice springs from a deep-seated desire in human nature, which the faculty will find it hard to eradicate.

In an article in the *British Medical Journal* the writer points out that there are now recognised three distinct types of influenza—affecting the respiratory organs, the nervous system, and the digestive organisation respectively. The epidemics with which we have been visited in recent years have been of all three types in succession, in the order we have mentioned, and that which is prevalent just now belongs to the third type. "The symptoms," says the writer, "are in many cases so severe and pronounced that the most experienced physicians have in individual cases felt some hesitation for several days in rejecting the diagnosis of typhoid fever." And he goes on to illustrate his point by the fact that in London, while influenza is on the increase, diseases of the respiratory organs are diminishing. It will be remembered, in connection with the Warwickshire epidemic, that while the general belief, shared in by many of the local doctors, was that the symptoms showed such derangement of the digestive organs as to point to poisoning, the Medical Superintendent of the Asylum adhered to his opinion that the outbreak should be characterised as a type of influenza.

Notwithstanding the serious epidemics of influenza which have prevailed during recent years, it is satisfactory to observe that the total death-rate for 1897 was only 17·4 per 1000, according to the returns of the Registrar-General for England and Wales. This, with the exception of the years 1894 and 1896, is the lowest death-rate on record since the establishment of civil registration in 1837. By a singular coincidence the birth-rate, which has shown an almost continuous decline for the past twenty years, was also last year the lowest since 1837, with the exception of the same two years, the rate for England and Wales being 29·7 per 1000 of the population, which is estimated at rather more than 31 millions of persons. Of the total deaths registered for England and Wales in 1897, twenty-five were attributable to small-pox, 12,456 to measles, 4492 to scarlet fever, 7461 to diphtheria, 10,887 to whooping cough, 4873 to fever (principally typhoid), and 26,857 to diarrhœa. The deaths from these principal zymotic diseases were thus in all 67,051, giving a death-rate of 2·15 per 1000. The decline in the number of deaths from small-pox is very striking. During the past five years the deaths from this cause have ranged from 223 to 1457, so that a decline to twenty-five is a result which is most satisfactory. Of these, sixteen were in London, and nine in the rest of the country.

Satisfactory as these results are, it is not satisfactory to note that an epidemic of small-pox has broken out at Middlesbrough, and that the disease is spreading to an alarming extent. The public vaccinator has been ordered to make a house-to-house visitation, and to vaccinate the inhabitants free of charge, for which purpose the services of three doctors have been retained. It has also been decided to close the lending departments of the free libraries and the lending library of the Literary and Philosophical Society. In presenting the report of the Public Health Committee of Edinburgh Corporation, the Convener, Bailie Pollard, took occasion the other day to comment on this outbreak, and to congratulate the people of Edinburgh on their comparative immunity from this scourge. He observed that they were quite prepared for any moderate outbreak of the disease, but he thought it well to remind the people that they did not need to have small-pox unless they wished it. The experience of the epidemic in Edinburgh four years ago, he said, had undoubtedly been that no person who had been properly vaccinated would take small-pox within seven years. The period of immunity in the case of young children is now thought to be somewhat less than this, but it is a wholesome standard on the average, and should be rigorously enforced on the least suspicion of an outbreak.

After an exhaustive investigation extending over eight days, the Local Government Board inquiry into the origin of the epidemic of typhoid at Maidstone was brought to a close last week. The Inspectors will doubtless present their report to the Local Government Board as soon as possible, but some time must necessarily elapse before it will be placed in the hands of the public. Meanwhile it is a matter for congratulation that the inquiry has been so thorough, and we think there can be little reasonable room for doubt as to the prime cause of the outbreak. The water company made resolute attempts to fix the responsibility on the drainage system, and they certainly succeeded in establishing the fact that it was hopelessly bad. It was shown that fully two-thirds of the houses in the town have for a long time past had no water laid into the closets, which were simply hand-flushed; and though the Sanitary Authority about four years ago began to attempt to reform this state of things, they showed so little energy in their enterprise that at the time of the outbreak no less than half the houses in Maidstone still possessed unflushed drains. Matters are proceeding differently now, no doubt, and the Sanitary Staff are pushing on the work of reform as fast as possible, but that is only after all the mischief has been done.

The drainage system of Maidstone has certainly been proved to have been wofully defective, but the weight of the evidence has shown that the real cause of the outbreak does not lie there. The testimony of the experts was almost unanimous in assigning the origin to the Farleigh water supply. It is true that the typhoid bacillus was not actually detected, but it was pointed out that this was hardly to be expected, as it is a thing most difficult to discover. On the other hand, the area of the epidemic coincided with the area of the water supply; a particular spring, which was found to be liable to pollution from fæcal matter, was proved on examination to be actually so polluted, and on cutting off the suspected source a marked improvement immediately followed. So much for the water company. But what will be thought of the policy of the Town Council, who totally neglected to have monthly analyses of the water taken? By this failure in their plain duty they imagined they were saving £40 a year, when in reality they were laying themselves open to the risk and the responsibility of a loss of £50,000, which, on a moderate estimate may be considered to have

been the cost to the community of this most lamentable epidemic.

Whatever may be thought of the prime cause of the outbreak, the Town Council have not shown up well in this inquiry. From motives of economy, it is to be supposed, they declined to engage the assistance of counsel, or to call expert evidence, and this because the Local Government Board, according to its regular practice, would not beforehand promise its sanction to this expenditure out of public money, though Mr. Davey stated that after the inquiry was over no doubt all legitimate expenses would be sanctioned. The inquiry was certainly non-judicial, but when counsel are engaged at all, it is better that all parties be equally represented, both in the interests of fairness in the examination of the witnesses, and out of regard to the time of the Court. The holding of a public inquiry, which was a departure from the usual course, has been abundantly justified by the result, for the facts have been ascertained with a fulness that could have been attained in no other way. And the chief lessons to be drawn from the investigation are the necessity for the strictest protection and supervision of all sources of water supply, and the paramount duty that rests upon the Sanitary Authority of making regular inspections and analyses of the water.

One result of the inquiry will undoubtedly be the arousing of public opinion, not only in Maidstone, but all over the country, to the importance of these lessons, as well as to the supreme importance of the establishment of a sound sanitary *régime* in every department. It will be realised by the ratepayers that money so spent is well spent. Sanitary Officers who are alive to their responsibilities do not need to have this elementary truth brought home to them, but those who hold the public purse-strings are often slow to view matters in the same light. There can be no more effective teacher, however, than a great public calamity, such as the Maidstone epidemic, and the light which has been thrown upon it by the Local Government Board inquiry. A Medical Officer may waste his breath for years in denouncing abuses which no one heeds, but the forcible instruction which is conveyed by a disastrous epidemic will make people see, as nothing else could do, the wisdom of his warnings.

Dr. Simpson, Professor of Medical Jurisprudence in Glasgow University, after occupying the chair for a quarter of a century, has retired, and the University Court is in some doubt as to the course that should be adopted in the appointment of his successor. By the constitution of the chair, the teaching of Medical Jurisprudence is to be associated with that of Public Health, and at the time when the chair was founded, early in the present century, this arrangement was possible and convenient. It is no longer so, however. Public health is now a subject of great and growing importance. In other Universities special provisions for its teaching are made, and diplomas in public health are granted, which have come to be recognised as valuable qualifications in Medical Officers. The subject demands a chair to itself. According to the present practice, the consequence of the association of the two subjects is that the more important subject is completely overshadowed by one whose utility is felt by only a very limited class. A generation ago that was no doubt in accordance with the fitness of things, for then public health had not risen to the position of supreme importance that it now occupies, but now that the position is reversed, it is felt that this opportunity should be taken to put matters on a true footing.

The difficulty is that an Act of Parliament is probably required to effect the change. It is felt to be a pity that the University Commission has not left it in the power of the University Court to separate the two subjects. Opinion in University circles is somewhat divided on the point, but the trend of opinion is that the requirements of Medical Jurisprudence would be amply satisfied by the appointment of a lecturer, who should be a man actively connected with the Courts; and that a Chair of Public Health should now be founded, whose occupant would be enabled to devote his whole time to his special subject, and particularly to work in the laboratory. The matter rests with Lord Balfour of Burleigh, the Secretary for Scotland. There is a widespread feeling that it would be well that he should delay making any permanent appointment until opinion on the subject has sufficiently matured, and to give those who are in favour of the foundation of a Chair of Public Health an opportunity to raise the necessary funds. It is quite imperative that in a leading medical school like that of Glasgow such a chair must be established before long, and it would be a thousand pities if by too precipitate action the present opportunity were to be lost.

An interesting case of unsound meat exposed for sale in a butcher's shop was recently decided by the magistrates of Alfreton. It appears that on the 11th January the Inspector of Nuisances of the Alfreton Urban District Council seized seven pieces of meat and one piece of sausage which it was alleged were unfit for human consumption. They were exposed in a butcher's shop belonging to the Ripley Co-operative Society, Limited. The seizure and subsequent condemnation by the magistrates appear to have been properly carried out under the provisions of Sections 116 and 117 of the Public Health Act, 1875, under which it is provided that a "Medical Officer of Health or Inspector of Nuisances may at all reasonable times inspect and examine any animal, carcase, meat, &c., exposed for sale, or deposited in any place for the purpose of sale, or of preparation for sale, and intended for the food of man, the proof that the same was not exposed or deposited for any such purpose or was not intended for the food of man resting with the party charged." It is further provided that the Justice may, if it appears to him that such meat, is diseased, condemn the same, and order it to be destroyed. Moreover, the person to whom the said meat belonged is adjudged liable to a penalty not exceeding £20 for every piece of meat, &c., so condemned.

There was put forward on behalf of the Society the customary plea that the meat was not intended

for sale for human food, but that it was sold for pigs or intended for sale for pigs. We confess we have some difficulty in comprehending how meat intended for the four-footed animals could be exposed for sale in a sale shop with meat avowedly intended for the food of man. If such a plea were to be held good by any other magistrates than those of Alfreton—for the case was dismissed—we should be sorry for the health and lives of the poorer classes in our towns for whom the provisions of the sections we have referred to were intended, as they need to be protected against the iniquity of meat being sold to them which is only fit for pigs, and which may produce disease and death. The Alfreton Council are, however, to be commended for their action in instituting — as guardians of the public health—the prosecution, and although the same failed through no fault of theirs, the effect cannot but be productive of good to the health and lives of the community of their particular district, as the prosecution will act as a warning to purveyors of food generally to exercise the utmost care in conducting their business on proper and legitimate methods.

NOTES ON
PRACTICAL SANITARY SCIENCE.

By WILLIAM H. MAXWELL.

No. 49.—REFUSE DESTRUCTORS.

(Continued from page 139.)

"Acme" Destructor.

The "Acme" refuse destructor[128] is the patent of Messrs. Hart and Royle, of Stretford, Manchester. Its general arrangement differs materially from those previously described, as will be observed from the accompanying Figs. 13 and 14. The working of this destructor is as follows:—The material to be burnt being placed in the hopper A gradually falls into the furnace B on the sloping bars, and after loss of its combustible matter, slides down into the ashpit I, from whence it can be removed at convenient intervals by means of a proper shovel, either at K or L. As the ashes, clinker, or purified refuse is removed, a fresh portion follows down the inclined bars, the place of which is immediately taken up by another portion of raw material descending from the hopper, this process proceeding continuously, or at such rate as material is found to emerge at K or L in a sufficiently burned condition.

At B is a new arrangement of furnace bars in the form of a step-bar grate, set at an angle of about 45 deg., with large spaces for the admission of air to increase the draught, so that no blowers for a forced draught are used by the patentees.

The feeding in of the material is said to be almost as gradual as though rocking bars were employed. The action of the hanging bridge, writes Mr. Royle[129], is also to be noted, "any vapour evolved from the raw material is deflected partly over the surface of, and partly actually through, the already incandescent portion, where it also meets the red-hot gases arising from the combustion of the lower portion and becoming ignited, finally passes through the combustion chambers, heating these to such a high temperature that no combustible vapour can escape. As each spadeful is withdrawn it is followed through the whole system by an equal volume of the raw material, the volatile matter from which being thus slowly evolved, has ample time for complete combustion, which cannot be the case where large charges are thrown on at one time. Although designed as a destructor only, it is as capable as any other of being adapted to the generating of steam when the material to be burned contains enough heat-producing material; it equally permits the use of rocking bars, as also the use of a steam or other blower being applied. For the latter purpose it is only necessary to close the front, as is usually done, and fix the necessary blower or fan."

The inventors of the "Acme" destructor claim for it that:—

(1) It can be constructed at less first cost than any other.

(2) For efficiency, for ease of working—that is, the feeding with raw and the removal of burnt material—it offers every advantage.

(3) That, from its simplicity and freedom from working parts, it is less liable to get out of order than any other, therefore will neither require expensive skilled labour nor incur frequent stoppages with consequent decrease of working time. Any repairs needed can be done by any ordinary blacksmith or bricklayer.

(4) That it effects complete combustion of all carbonaceous or other organic matter in a systematic manner, all vapours having to pass through red-hot material and highly-heated combustion chambers, thus rendering the escape of noxious gases impossible.

In regard to the capabilities of the "Acme" as a steam producer, and as to the question of utilisation of heat generated by destructors generally, the inventors express the following opinions:—"It is impossible to forecast this amount until experiments have shown what amount is given by them when in actual work, the conditions being so various. To this end we recommend that a boiler should not be put down until this has been ascertained. The amount of combustible matter may be more or less in the refuse of one town or place than another, and therefore the heat generated be more or less; and as a boiler should be proportionable in dimensions to the amount of fuel used, until this is known it is impossible to give accurate dimensions. We are confident that our destructor will give out the full calorific value of the burnable matter in the refuse."

The "Acme" furnace is also claimed to be a "fume cremator" in itself, so that any additional provision in this direction would be superfluous. The furnaces are simple in construction, and have a grate area or fire-bar space of 36 square feet. The cost of erection is given at about £180 per cell, including roadway over the cells and royalty.

Some furnaces of this type, fitted with "Step-Bar Grates," are in use at Messrs. Tennant and

[128] Patent No. 8732 (1892).

[129] *Vide* paper on "The Acme Refuse Destructor," by H. Royle, A.M.I.C.E., read at the Liverpool Congress of the Sanitary Institute, 1894.

Company's Chemical Works, Mill-street, Clayton. At Messrs. Tennant's works a trial has recently been made in the burning of town refuse in two small grates, each 4ft. by 1ft. 6in., *i.e.*, 12 square feet area. In these six loads of refuse were burnt in 33·5 hours, being ·179, or about one-sixth of a load per hour. Unfortunately the loads were not weighed, but assuming the weight of each at 24 cwt., the consumption was at the rate of $\left(\frac{24}{6}\right)$ 4 cwt. per hour, *i.e.*, $\frac{4 \text{ cwt.}}{12 \text{ sq. ft. grate area}} = 33$ cwt. per foot grate area per hour. There was no forced draught the draught, on the contrary, was slight in comparison with that ordinarily obtainable in connection with a tall destructor chimney, and the smallness of the furnaces was unfavourable to the test.

THE SANITATION OF DOMESTIC BUILDINGS.

By Frank Latham, C.E., M. San. Inst., &c., Assistant Surveyor, Borough of Margate.

CHAPTER IV.

Section 1.

TRAPS AND GULLIES.

Traps are arrangements in connection with drains which arrest the flow of air or gas into, out of, or along a pipe, and where the sewage or water automatically forms the seal.

Gullies are special forms of traps placed on drains or at the end of branches to give free inlet to waste waters and other matters, and at the same time prevent the escape of any air or gas from the drain, either when the gully is in action or not. There can be no doubt that the question of traps

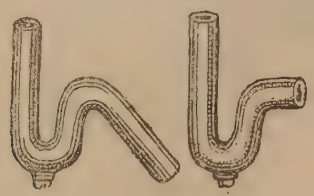

Fig. 27.

requires close attention, as these are the principal barriers relied upon to arrest the foul air present in drains and prevent its escaping into houses or other places where its effects might be injurious to health. Their internal surfaces should be as small as possible compatible with efficiency, and fitted with suitable arrangements for inspection and cleansing. Every sanitary arrangement in connection with the drains and inside of houses should be trapped, and the trap fixed as close to the apparatus as possible in order to leave no portion of the connecting pipe open to the internal air.

To effectually prevent the passage of drain air, every waste pipe from apparatus inside houses, with the exception of w.c.'s, urinals, and slop sinks; such as scullery sinks, lavatory basins,

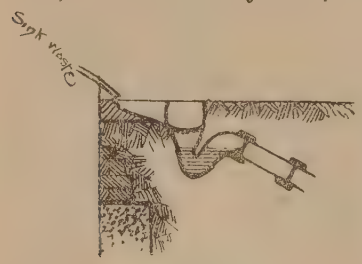

Fig. 28.

Fig. 29.

baths, &c., after being trapped by means of a syphon trap (Fig. 27), should be taken through an external wall and made to discharge in the open air, over a channel leading to a properly-trapped gully. (Fig. 28.) In the case of the waste pipe being on a higher floor than the gully, it should be connected with a special waste pipe carried up with an open end as a ventilator, and discharging in the open air at the foot. These wastes are, however, in some towns made to discharge by means of a "swan-neck" into an open cistern head (Fig. 29) leading to a gully trap, which is not to be recommended, owing to the cistern-head becoming very foul. The "Model Bye-laws" of the Local Government Board require wastes to discharge over a channel at least 18in. distant from the gully, and this condition successfully answers two purposes, viz., in the case of the escape of drain air through the gully, the waste pipe will be sufficiently far away as to be out of danger as an intake; and, again, in the case of sinks, the water and grease will have an opportunity of cooling before entering the drains by

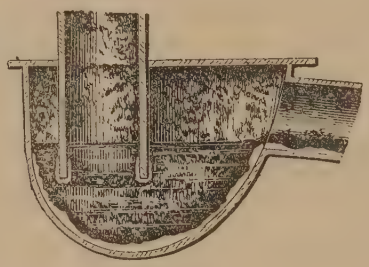

Fig. 30.

being exposed to the open air—another good feature in this arrangement. Overflow pipes from cisterns, and all descriptions of safes, should not in any case be made to discharge directly over a gully, but in some suitable, conspicuous position, where waste of water would be immediately detected, and the cause remedied.

All rain-water pipes for the conveyance of water off roofs should discharge at the foot in the open air over trapped gullies. By so doing, should the gully become stopped, it can easily be cleaned out, and in cases of drought where there is insufficient

Fig. 31.

rain to seal these traps, they can be regularly attended to and the water supply replenished, but if the pipes were connected up directly with the trap, upon the latter becoming stopped, there being no means of access for cleansing purposes, the water must rise and stagnate in the pipes or escape through the joints and cause damp walls, whilst in the time of drought the trap upon becoming unsealed would allow the drain air to ventilate up these down pipes and cause a nuisance. It is a mistake to make openings in drains to receive small and intermittent quantities of water, as there may not be sufficient usage of the gully to remain sealed, therefore in all cases of this description, where such connections are required a second waste pipe from a scullery sink or bath should

also be taken into it in order to keep the gully charged.

Gullies should never be placed inside houses; it is a dangerous practice so to do, as the most evil results must necessarily follow, either through the trap becoming dry or the drain air forcing itself through the water seal. All gullies should therefore be placed outside in the external air, and all waste pipes made to discharge with open ends also in the external air.

It is an important feature to have the waste

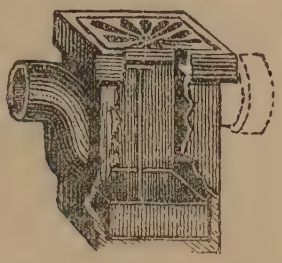

Fig. 32.

pipes of apparatus, such as scullery sinks, baths, and lavatory basins, trapped, although some may argue that owing to these being disconnected and made to discharge in the open air over gully traps there is no necessity for so doing, and, further, that traps are a disadvantage as the water is obstructed in its flow. But it is obvious that such traps, besides shutting out of the house any smells that may emanate from the filth in the gully trap and waste pipe, &c., prevent, in case the gully becomes unsealed through defect or otherwise, the escape of drain air, which, owing to the warmth of the inside of the house, as compared with that of the outside, may be drawn or blown through the sink

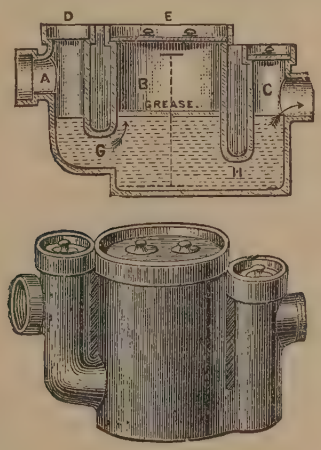

Fig. 33.

waste. It is a frequent occurrence that in removing the bucket of the sink gully for cleansing purposes the water-line is lowered, and sometimes the trap left unsealed until the sink is again used. This would certainly give a facility for the admission of drain air into the house should there be no proper trap to the sink waste. Again, if not for the trap, the waste pipe itself being corroded with decomposing matter, would be a vehicle for fouling and passing tainted air into the interior of the house. In the case of baths and lavatory basins, these arrangements are generally situate above the ground floor, and have, therefore, long lengths of waste pipe, and although there may be sufficient disconnections in their course the results will not be satisfactory unless the bath is trapped, as after a time the pipes become coated with grease and other filth, and throw off objectionable effluvia, which is liable to be drawn into the interior of the dwelling.

It takes a good deal of discretion in selecting the best trap for various purposes, there being such a variety to choose from. The form of trap suitable should therefore be considered in conjunction with the position and purpose for which it is required. Good traps should have a dip of not less than 2in., to prevent their becoming unsealed.

The two principal enemies which traps have to fight against are syphonage, and the excess of air pressure to which drains are occasionally subjected. Syphonage is caused by a vacuum set up in drains. This is occasioned chiefly by the ventilation being insufficient and being so a sudden flush immediately sucks the water out of the nearest trap to give ingress to the required amount of air displaced, and thus leaving the trap open for the escape of drain air into the house. The excess of air pressure in drains is again a matter of ventilation, which owing to the momentum and force of the water passing through the drain an amount of air is displaced in its course, this air forcing its way through the least resisting outlet, and should there be no ventilation pipe it will escape through the water seal of the nearest trap. It therefore shows that a good dip should always be insisted on, especially in the case of those traps which are subjected to sudden and rapid flushing, under which circumstances they are liable to run themselves unsealed. Too much care cannot be exercised in fixing traps, as often a good trap will be rendered useless by being badly fixed. For instance, traps should be kept perfectly upright, and not allowed to fall over towards the front, for if this be the case they will not form the trap required, and perhaps will not seal. They should also be made of the same materials as the drains, with which they connect, so that they can be satisfactorily jointed, as it would be almost as well to have no trap as bad joints.

Gullies when at the ends of branch drains should always be set up in connection with the drain on a good bed of cement concrete, and well surrounded with that material. By so doing the trap is not only materially strengthened, but at the same time, is afforded that additional support required for the ends of the branches, especially as the trap is of extra weight, and as a rule, furnished with very little bearing surface. The manner of jointing gullies with the ends of drains should be noted. As a rule, the outlet of gully with a strand or two of gasket fastened round it is placed into the socket of the drain pipe and the joint cemented up. This, although the general way, is not quite satisfactory, it being difficult to make a good and perfect joint without proper access to the interior of the pipes, which cannot be obtained through the trap. To gain this access the last length of pipes to which the gully is to be fixed should have an inspection eye or square junction at the top, which, upon the joint being finished, and any surplus material inside the pipe removed should be closed over with a proper stoneware

stopper and cemented down. It is a mistake to use gullies and traps larger than is necessary, but no gully should be less than 4in. inlet, at the same time, a 4in. gully with 6in. outlet is sufficient for a 6in. drain for most ordinary purposes. The traps known as the D and Bell traps should never be used in modern drainage; the D trap (Fig. 30) being anything but cleanly, and the Bell very unreliable. (Fig. 31.)

To prevent the drains becoming coated with grease, which frequently is the cause of much trouble and derangement, proper grease-traps should be fixed to receive the sink waste water in

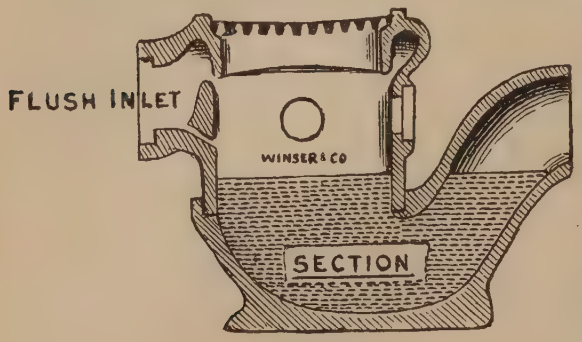

Fig. 34.

order that any fat that may exist may either be intercepted or cooled before entering the house drains.

Fig. 32 shows an ordinary small grease-trap with bucket. This trap is of little use unless the grease is regularly removed and trap cleansed.

Fig. 33 illustrates Buchan's patent grease-trap. This trap is manufactured by Messrs. Craig, and is one of the best of its kind. The sink waste water passes under G and H before entering the drain at C, giving the grease good opportunity of either collecting in the principal chamber B, and readily removed at E, or of becoming set, and thus not clogging the drain.

Fig. 34 is a grease-trap with flushing rim to enable the contents to be occasionally flushed out by means of an automatic syphon cistern.

THE MAIDSTONE INQUIRY.

The Maidstone inquiry having been brought to an end the Inspectors will, no doubt, report to the Local Government Board with as little delay as possible, though some time must elapse before their conclusions can be made known. Meanwhile, it is worth noting, remarks the *Standard*, that the experiment of holding a public investigation, which had been reluctantly agreed to as a departure from the normal procedure, has been justified by the result. It has occupied the time of three Government Inspectors for eight days, and has put some money into the lawyers' pockets, but it has at the same time ensured a much more minute examination of the facts than could have been obtained in any other way. The proceedings have been watched by a number of persons interested in different aspects of the main question, and have elicited a great many details which would otherwise have escaped attention. It is not too much to say that no epidemic has ever been so exhaustively examined; this fact alone would make the method of inquiry a matter of congratulation. There is only one thing to regret about it, and as the precedent may be followed on some future occasion, it should not be passed over. The decision of the Town Council neither to engage counsel nor to call expert evidence was a distinct blunder. Their motives, as explained by their own solicitor in open court, do them little credit. According to him, they originally asked for the inquiry because they thought it would assist them in recovering from the water company the expenses incurred in consequence of the epidemic; but when they discovered that they had no claim against the company, their interest in the affair greatly diminished. The Local Government Board, following its regular practice, declined to give preliminary sanction to the payment of fees for counsel and expert witnesses out of public money, whereupon the Town Council resolved to show their dissatisfaction by engaging neither. Mr. J. S. Davey, the presiding Inspector, stated in plain terms that the inquiry was not held to assist the Town Council in bringing an action against the Water Company, but, in the public interest, to ascertain the facts; and he intimated that the Local Government Board would doubtless sanction all legitimate expenses after the inquiry was over. The Authorities, however, remained unmoved, and eventually Mr. Davey had to make himself personally responsible for the expense of calling Dr. Washbourn, a most important witness. The conduct of the Town Council is, however, thrown into stronger relief by the action of the Water Company, which has behaved extremely well throughout, and promptly offered to share the expense, although Dr. Washbourn was a hostile witness. In the end he was called, and gave evidence, to the great advantage of the inquiry. But the Town Council remained unrepresented by counsel throughout, thereby exposing their own witnesses to the unfair ordeal of a forensic cross-examination without adequate protection, and encouraging a reckless disregard of legal procedure. In non-judicial inquiries of this kind the strict rules of a Court of Justice are not observed, nor is it desirable that they should be; but some order with regard to evidence ought to be insisted on, or the cross-examinations and re-examinations may go on for ever. The only way to keep a clever counsel in check is to have an equally able advocate opposed to him, and for want of one in this case much time was uselessly lost, and witnesses were needlessly worried.

With regard to the cause of the outbreak, the general upshot of the inquiry has been to confirm the opinion previously formed, and to fix the responsibility on the Farleigh water supply. Heroic efforts have been made to shift it on to the drains, with the admirable result of exposing the neglect of owners of house property and the supineness of the Sanitary Authority. That is one of the great advantages of a public investigation. It has laid bare a state of things which no one can attempt to defend, and in doing so it has ensured, as nothing else could, a speedy reform. Abuses which the Medical Officer has vainly denounced for years will now be swept away by the general demand of the community. It appears

that for a long time past, out of six thousand houses in the town, about four thousand, or two-thirds of the whole, have had no water laid into the closets which were hand-flushed. Four years ago the Sanitary Authority began to use the powers it possesses, but was so tender of putting pressure on the owners of all this insanitary property that reform only proceeded at the rate of about two hundred houses a year. At this pace it would have taken just twenty years to complete, and when the epidemic arose it found Maidstone still in the enjoyment of some three thousand unflushed house drains. Now, we are informed, the work is proceeding in a very different fashion, and as rapidly as an increased staff can get on with it. No doubt; but meantime those three thousand unflushed drains have put a weapon in the hands of the Water Company which their adroit advocate flourished in the face of the Town Council with great effect. It may have unsettled the minds of some of the inhabitants, as it was probably intended to do, but of course it will not in the least impose upon the Government Inspectors. Bad as the drains are, and very likely responsible in some measure for the continuance of the fever, the exposure of their defects does not weaken the case against the water as the primary origin. Absolute proof of the precise causation of an epidemic like this cannot be expected; it is never obtained, and probably never will be, on account of the complexity of the questions involved, and the length of time which must elapse before investigation can be made. But the chain of evidence in the Maidstone outbreak is only short of absolute demonstration. Its character was typical of water-borne disease; the incidence corresponded with the water supply, and with nothing else; the cutting off of the suspected source was followed by marked subsidence; a particular spring was found open to specific pollution, and proved on examination to be so polluted; lastly, the precise manner in which the pollution probably took place was explained by the extremely interesting and original observations of Dr. Adams on the rainfall and the subsoil water. It would be mere affectation to pretend to a scientific suspension of judgment in the face of these facts. If the cause of the epidemic has not been proved, as some hairsplitting gentlemen are pleased to maintain, then the cause of no epidemic on record can be said to have been proved, and sanitary science may as well begin all over again.

Whether the occurrence could have been foreseen or not is, perhaps, open to question; but it is quite certain that none of the parties concerned are in a position to throw stones at the others. If the Water Company gathered their water from a dangerous source, the Town Council never troubled their heads about it, and in a spirit of miserable parsimony deliberately abandoned monthly analysis, their only safeguard. It was little enough, but it might have sufficed, if not to prevent, at least to cut short the trouble at the outset. They preferred to save forty pounds a year and run the risk of losing fifty thousand pounds—a moderate estimate of what the epidemic has cost. The ratepayers, for their part, not only sanctioned that policy, but refused, so late as 1896, to take the supply into their own hands. If blame is to be distributed, there is enough to go all round. It is pleasanter to distribute the praise. The inquiry has brought out very plainly the admirable manner in which the emergency was met by everyone concerned. The organisation for the care and relief of the sick, and the protection of the healthy, was most complete. The Town Council spared neither money, nor time, nor trouble. The water company, and especially the manager, Mr. Ware, gave all the assistance in their power, and promptly complied with every sug gestion. Finally, the Medical Officer and his deputy, Mr. Percy Adams, to whom the main bulk of the work fell, distinguished themselves by equal zeal and capacity. These are matters of local interest, but there are others of much wider importance. There is the adequate protection of gathering grounds, the duty of regularly inspecting them, which involves legal right of access by the Sanitary Authority, and the necessity of making frequent analyses of water. Incidentally, also, the question of hop-pickers and other seasonal immigrants has been raised. It is a difficult thing to deal with, but some reform of the arrangements prevailing in the neighbourhood of Maidstone is imperatively needed. It will be the duty of the Kent County Council to see to it before next season.

FROM WHENCE CAME THE FEVER TO LYNN?

DR. ST. GEORGE MIVART INVESTIGATES AND REPORTS.

It is barely four months since the news was published that a serious outbreak of enteric fever had taken place at King's Lynn. The announcement created considerable consternation, for at that time the epidemic at Maidstone was raging with unabated force, and fears were entertained that the country at large was about to be visited with a plague of typhoid. Happily the fresh outbreak proved only local, and though violent for a time, its virulence was spent within a month or so. Still the fact of such a visitation being possible was sufficient to call for a stringent inquiry by the Local Government Board, and Dr. St. George Mivart was sent down to Lynn to ascertain the source from which the contagion arose.

His report has just been issued, and we cannot think it is pleasant reading for the Town Councillors and inhabitants of King's Lynn, for it is the old story of warnings neglected, and a refusal to learn by experience. Dr. Mivart prefaces his report with a reference to former epidemics, and briefly traces by means of tables the progress of the outbreak last October. Taking the six fortnights ending November 23rd, he found the following notifications were received :—

	Houses invaded.	Cases.
Ending Sept. 14th	4	4
,, 28th	4	4
Oct. 12th	5	9
,, 26th	183	214
Nov. 9th	139	172
,, 23rd	23	42

In the last week of November two houses were invaded, the persons attacked numbering eight. Commenting on the statistics, Dr. Mivart says that "In 1897 to the end of August, Lynn and its neighbourhood suffered no more than the customary

amount of enteric fever. Next, during successive fortnights of September, and in early October, this disease became twice to three times as prevalent as in any previous month of the year. Then occurred an extraordinary outbreak of enteric fever. In the fortnight ending October 26th fever in Lynn and Gaywood increased thirty to fortyfold, and maintained during the next succeeding fortnight a nearly equal degree of prevalence. Afterwards it quickly declined; so that by the beginning of December the epidemic as such was practically at an end. In all, there occurred in Lynn and its neighbourhood between September 1st and November 30th 453 cases and 44 deaths referred to enteric fever—an attack-rate by the disease of 23·45, and a death-rate of 2·28 per 1000 of the census population."

In an analysis of the age incidence it is shown that 42 cases were reported under 5 years of age, 79 between 5 and 10, 100 between 10 to 15, 118 from 15 to 25, 37 from 25 to 35, and 29 from 35 upwards.

The "Causation of the Epidemic" is next dealt with, and in seeking explanation, says the Inspector, "It has to be borne in mind that the outbreak occurred suddenly; that it appeared simultaneously in the town of Lynn and its suburb Gaywood; and that from first to last (especially in the fortnight of its chief incidence) the fever was distributed throughout the length and breadth of both places. Outbursts of enteric fever such as this—so sudden and so widespread throughout a large and populous area—have again and again been referred on incontestable evidence to specific pollution of public water supplies. In the particular instance, the past history of Lynn and Gaywood, along with the facts respecting their present fever and their circumstances at the date of my arrival in the place, afforded a strong presumption that the epidemic was due to the faulty character of the public water service. I did not, however, accept such presumption, preferring rather to examine, as matter of first instance, other accredited agents of enteric fever, some of which had been thought of locally as quite as likely as the water supply to be responsible for the fever which was occurring. In this way I came to be concerned with (1) sewerage and drainage; (2) general sanitary circumstances; and (3) milk supply, as possible causes of the outbreak."

The Medical Officer, Dr. Bruce Low, in his report on an outbreak of enteric fever, of a very similar though less extensive character at King's Lynn in 1892, thus describes the sewerage of Lynn:—"The public drainage consists, in the older parts of King's Lynn, of short sections of brick sewers constructed some years ago, and discharging by different outfalls directly into the Ouse or into one or other of the fleets. For the northern and eastern part of the town a long length of sewer was a few years ago laid down. This sewer, which receives the sewage of more than half of the houses in the town, has an outfall near the old dock and is generally known as the 'dock culvert.' For a considerable distance it is an egg-shaped brick sewer, and throughout it is ventilated at intervals by openings at the street level. Here and there shafts have been carried up above the level of the house roofs. There are several automatic flushing tanks at the ends of branch sewers. Few of the sewers appear to be self-cleansing. Deposit takes place in nearly all of them. The tide dams up the sewage in all for several hours daily. Private drainage is effected by ordinary pipe drains. Gullies in yards are mostly trapped. Rainfall pipes usually pass directly into the drains. In some cases sink pipes are not disconnected, but the majority of houses have no sinks indoors. Soil pipes in some cases are ventilated; much improvement in this respect has been effected of late." And as regards Gaywood he says:—"The sewers of King's Lynn extend into the village of Gaywood. There are roadway ventilators along the main sewer, and a flushing tank is situated at a point where the sewer from Gaywood joins the borough main sewer."

As regards sewerage, the above description may be taken as describing to a very large extent the present condition of Lynn. Certain lengths of brick culvert sewer, which were specially defective, have been replaced by pipe sewers, but the general arrangement remains the same, and the sewage is still tide-locked for several hours daily. When an exceptionally heavy rainfall occurs at the time the sewers are thus closed by the tide, more or less extensive flooding is caused of streets, yards, and even of houses.

Two exceptionally heavy rainfalls occurred in August and September. The town was flooded, in some parts the water coming from the drains and sewers being almost black, and when it subsided a foul-smelling deposit remained behind. An investigation was made as to prevalence of fever in houses situated in the parts where the flood was most severe, but it was found that there was nothing exceptional followed; and after carefully considering all the circumstances Dr. Mivart concludes that "faulty sewerage and drainage are not responsible for the sudden outburst of enteric fever."

With regard to the general sanitary circumstances, reports by Mr. W. Whitaker, F.R.S., and Dr. Bruce Low are quoted to show the condition of Lynn at the time of the former outbreak in 1892. Dr. Mivart says:—"There is crowding of houses upon area at certain points, but I met with no instances of overcrowding of persons. There is no doubt that the Sanitary Committee have effected improvements since the last epidemic of enteric fever in 1892. In many of the closest and most crowded courts and alleys I found that water-closets, fitted with flushing cisterns, had been provided, though, it must be added, not a few were out of order and in a foul condition. It is also still the fact that, as stated by Dr. Low in his report, in some courts the closet accommodation is inadequate, and the privies are too close to the dwellings. Notable instances of this were seen in the vicinity of Windsor-road. Leading out of this thoroughfare are certain streets of cottage residences, many of which had cesspit privies in a foul condition. Moreover, the backs and sides of the brickwork are not rendered in cement, and in some cases I detected cracks which must allow free soakage from the privy into the adjoining premises. The arrangements for the emptying of privy pits are very defective. Upon the application of the householder the contents of cesspits are removed in iron tank carts belonging to the Corporation. As Dr. Low observes: 'In the process of emptying some privy pits the contents have to be carried through the houses.'

"Nevertheless, I did not find that the incidence of the fever had been heavier upon the inhabitants of the worst class of dwellings, or that the epidemic outburst in October had specially affected the least wholesome quarters of the town. Up to the date of my last visit I found that not a few of the closest courts and alleys had either altogether escaped the visitation, or that at most single cases, often of a mild type, had occurred in them. On the other hand, on certain residences which could not be classed among those styled poor, the incidence of fever had been very severe. In particular, I visited two dwellings, of the superior type of small house, in each of which five cases and one death had occurred. In neither of these houses were conspicuous sanitary defects to be found. The water-closets were outside the houses, and the only defect worthy of note was that in one case the scullery waste pipe (which was not trapped) delivered outside the house, too close to the gully hole, the exit of the waste pipe being actually below the 'grid' covering of the gully. But as this was open to the air, it could not be contended that there was direct communication with the sewer. As I have said, upon the whole there was absence of any evidence that general sanitary circumstances had been responsible for the simultaneous appearance of cases of enteric fever throughout the district."

A very brief inquiry into the milk supply was sufficient to set aside the suggestion that milk had been the means of conveying the disease. Next week we shall refer to that portion of the report dealing with the water supply.

THE INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH.

DR. SERGEANT ON "INSPECTION OF COWSHEDS."

A MEETING of the members of the Incorporated Society of Medical Officers of Health was held on Friday evening, 11th February, 1898, at the offices of the St. Giles's District Board of Works, 197, High Holborn, W.C. Dr. E. Seaton, Medical Officer of Health to the Surrey County Council, the President of the Society, occupied the chair, and there was a good attendance, including Drs. Armstrong, Cameron, Bond, Willoughby, Groves, and Allen.

Dr. E. SERGEANT read a paper on "Inspection of Cowsheds," taking as the basis of his remarks a resolution passed by the North-Western branch of the Association: "That in order to secure greater efficiency and uniformity in carrying out the regulation under the Local Government Board Orders relating to dairies, cowsheds, and milkshops, it is desirable that the responsibility of inspection should be entrusted to the County Councils concurrently with the existing Urban and Rural Authorities." The necessity, he said, of obtaining the greatest purity in our milk supplies was evident when it was remembered how extensively cows' milk is used by all classes, and not unfrequently forms the sole sustenance of human life. Quoting figures of the late Mr. Ernest Hart, he showed how many deaths were due to epidemics occurring through the agency of milk, and it was suggested from long experience that these figures, striking as they were, only touched the fringe of the subject. Such outbreaks of disease might be entirely prevented, yet it must be admitted that the experience gained during the last twenty years had not borne the fruit which it should have done and did no credit to the boasted advancement of civilisation. There was an imperative need for the rigid enforcement of regulations for the inspection and periodical examination by competent Inspectors of all cowsheds, dairies, and milkshops. When the prevalence of tuberculosis among animals was remembered the danger to consumers could be properly appreciated. Experience showed in no uncertain manner that the supervision existing by Sanitary Authorities outside London is, with comparatively few exceptions, a delusion and a snare; as a whole their inspection is in no way calculated to protect the public from contaminated milk. Rural Authorities had adopted the mistaken policy of non-interference, and cowkeepers were indifferent to the dangers incurred by a distant milk-consuming public. To save the expense of a few pounds, filth, overcrowding, and badly ventilated sheds were allowed to remain. Many Authorities discouraged the action of their officials and suspicion naturally attached to milk produced by dairymen who could give no guarantee that their milk is provided under sanitary conditions. Such indifference to the needs of the case was greatly to the discredit of Local Authorites, and called for prompt action. In the majority of regulations now adopted no standard for cubic space is allowed at all, and consequently the Sanitary Inspector was in a difficulty in securing the necessary improvements. He thought that the minimum cubic air space should be 800ft. for each animal, and many difficulties would be avoided if Sanitary Authorities throughout the country had the same standard to guide them. There was no good reason why cowsheds should not be subjected to one standard rule laid down by the Local Government Board. In a considerable number of districts no cowsheds or dairies were registered at all, so that very little sanitary control could be exercised over the milk trade, and mostly the whole matter had to be left to the discretion of the Sanitary Inspector as to whether to go and what to insist upon. There were no regulations as to drainage, water supply, flooring, or cleanliness, so that Inspectors were often in the dilemma of knowing that the insanitary conditions prevailed, yet could not enforce improvements because of the absence of standards or regulations and bye-laws. Dr. Sergeant laid it down that (*a*) the supervision of cowsheds generally is far from satisfactory; (*b*) that regulations are only partially adopted, and not always with the intention of being put into force; (*c*) that the action taken in districts is wanting in uniformity and efficiency owing to different methods of inspection carried out by the various Authorities; (*d*) that milk is frequently distributed to distant communities possessing no power of control over its production, and without a sufficient check against the introduction of disease and contamination. As a remedy he suggested (1) the carrying out of the Dairies, Cowsheds, and Milkshops Order be made compulsory throughout the country in accordance with regulations from time to time issued by the Local Government Board; (2) regulations for the ventilation, drainage, water supply, and cleansing of cowsheds. (3) the periodical inspection of cattle; and (4)

precautions for ensuring cleanliness by dairy farmers and milk sellers, so that the milk should not become contaminated during transit. He believed if these or similar regulations were enforced, the public health would no longer be in danger, and the outbreaks of milk-borne disease, which played such havoc would entirely disappear.

An interesting discussion, in which the Chairman, Dr. Armstrong, Dr. Groves, and others took part, ensued, with the result that it was unanimously resolved, on the motion of Dr. SERGEANT, seconded by Dr. ARMSTRONG, "That in order to secure greater efficiency and uniformity in carrying out the regulations under the Local Government Board's Orders relating to dairies, cowsheds, and milkshops, it is desirable that the responsibility of inspection should be entrusted to County Councils, concurrently with the existing Urban and Rural Authorities." It was further resolved, "That model bye-laws should be framed by the Local Government Board for the regulation of dairies and cowsheds throughout the country, so as to ensure uniformity and efficiency" These regulations were referred to the Council for the purpose of submission to the proper quarters.

A hearty vote of thanks to the Chairman closed the interesting proceedings.

THE SANITARY INSTITUTE.

PURIFICATION OF WATER FOR BARRACKS, PRISONS, AND OTHER INSTITUTIONS.

A SESSIONAL meeting of the members of the Sanitary Institute was held on Wednesday, February 9th, at the Parkes Museum, Margaret-street, when Dr. C. Louis Parkes, M.D., D.P.H. (London University), presided over a good attendance.

Professor J. LANE NOTTER, M.A., M.D. (Dub.), delivered a lecture on the "Purification of Water for Barracks, Prisons, and other Institutions." He said that when large institutions are being dealt with in regard to their water supply something more is required than ordinary domestic filtration for the purification of the water. But at the outset it was absolutely necessary that the source of the supply should be above suspicion. No system of purification would render a water supply under any conditions perfectly safe. Now the system of purification of any suspected water had generally been by filtration, either on the non-pressure system or with pressure, and filters could be divided into those with pressure and those without. Of the non-pressure filters in use mostly up to the present time perhaps animal charcoal was the most common. But animal charcoal contained phosphates and nitrogen, and from experiments he had no hesitation in affirming that it forms an admirable breeding ground for micro-organisms; therefore it was considered an unsafe medium for water filtration. It also had the objection of allowing organic matter to pass through unchanged. Perhaps the

SUBSTANCE MOST IN USE

next was spongy iron, which acted as a filter owing to its fine state of division. The chief objection to spongy iron was that it did not sterilise water, removing only from 40 to 50 per cent. of the micro-organisms, increases the free ammonia, and had a tendency to coke, while it also added iron to the water. With the exception of sand filters, he knew of no filter for domestic purposes which would sterilise water. The second class of filters—the pressure filters—were those of the Pasteur-Chamberland type, made of China clay, the pores being extremely fine. In every experiment he had made the Pasteur filter had sterilised water, but the difficulty in connection with it was that of the joints, and where it was used for military purposes this formed one of the chief objections. The liability to fracture and the difficulty of plugging up the holes afterwards limited its use for military purposes, except for barracks and similar institutions, where proper supervision could be carried out and where much movement was not required. Where plenty of time could be allowed for the filtration, so far as he knew this was one of the best classes of filtration that they had at the present day. But he thought that the thickness of the material was not enough, and that there ought to be more rapid filtration. Having referred to other classes of filters, the lecturer said that the great difficulty was the

QUESTION OF CLEANSING

them and keeping them in order. How could they keep them in order so that they might always be relied upon to act? In active military life it was extremely difficult to get the soldier to do this, for the soldier generally had a disregard as to whether water was filtered or not. Besides, except where there was a public water supply these filters could not be used because pressure is required, and that pressure must not be too extreme, or the micro-organisms would be driven through. These filters had no chemical action on water, they simply sterilised it; they did their work well, and, if proper attention was paid to them, seemed to afford every security. But if they were dealing with water very different to that which is obtained at home, water containing growths of desmidiæ and diatomacæ, rapidly flourishing under a high temperature, he had known these filters to get so coated as to almost prevent the water passing through within a comparatively short time. This could of course be remedied by constant cleaning.

FOR SMALL DISTRICTS,

schools, barracks, and prisons, a sand filter often proved invaluable. He knew of one not far from London, put up by Mr. Rogers Field, which had worked perfectly. One point he desired to emphasise, and that was that there should not be a duplicate water supply in any place, because where two systems existed there was always a danger. People would not take the trouble to distinguish between one tap and another. Also the placing of a large number of small filters in one institution was a thing they all decried. The water supply of large institutions in which a number of people were congregated ought to be supplied filtered and fit for drinking on a large scale, and the best method for this was a sand filter. He had seen in many places a sand filter, properly constructed, properly laid, and of sufficient depth, with the rate of flow guarded against being too excessive, yield as a rule pure water, unless originally it was in a bad condition. It certainly would render ordinary water purified in the majority of cases. But there

were perhaps certain conditions under which of all others they could not depend upon filtration at all, but such conditions were seldom to be found in civilised life. These were the conditions of water met with in

ACTIVE MILITARY OPERATIONS,

and the question then arose, "Is it possible to add anything to water that will render it absolutely sterile?" "Is it possible with our present knowledge of infectious disease to so render water sterile without submitting it in any way to filtering action?" He had lately been making some experiments with regard to this, and so far he had been eminently successful. During those experiments he had found certain things occur which increased our knowledge of the whole subject. In Germany a few months ago it was suggested to add to suspected water a certain solution of bromine, and afterwards to decolorise it by using a solution of hydro-sulphate of sodium. He had made a number of experiments to test this, as it would be invaluable in many cases in which filters failed, or in circumstances in which filtration was not possible. They were done under conditions which he thought admitted of no fallacies. Giving the details of these experiments, the lecturer showed that he had been able to sterilise water infected with the typhoid bacillus by adding a certain quantity of bromine. The colour was removed by a certain proportion of sodium hydro-sulphate and sodium carbonate. The water had a pleasant sharp taste, and no odour of bromine could be detected. They often heard of the antagonism which exists between chemical and bacteriological examination, but here he thought one helped the other. In these experiments, forty in number, he could not help noticing how the presence of organic matter in the water influenced more or less the growth of pathogenic forms in the water. In perfectly

PURE DISTILLED WATER

they appeared to have no effect whatever, but directly a water was made impure they appeared not only to remain in the water, but to amplify largely; at any rate, they appeared to increase in number. It was often said that chemical analysis gave no indication, but he thought that, on the contrary, it gave a very excellent indication; it tells of a condition of water which, if a specific organism is introduced, is likely to spread, to multiply and propagate itself. In distilled water these organisms did not appear to increase; whether they died or or not he was not at present quite certain. This showed that they must, to a large extent, rely on chemical analysis to show the condition of water, and on the bacteriological examination to define what the organic matter really is, whether it is due, as it might be, to animal pollution, or simply to vegetable organisms. This principle which he had mentioned had been exercising their thoughts a great deal lately on account of the excess of enteric fever in the far northern country of India, where it is impossible to resort to a system of filtration and those means of purifying water which are found in England to-day. If they could, by adding to water some solution such as he had indicated to render water sterile, he thought they might to a certain extent reduce the mortality from that disease in tropical countries where it proved so fatal.

ANOTHER METHOD

had been introduced, he was not sure by whom, as coming from Vienna last year, but he did not think it gave such good results as those he had mentioned. He alluded to calcium hypochlorite, and the only difficulty he found with it was that of dissolving the salt. These experiments, however, were all very recent, and he should be sorry to accept them yet, but gave them for what they were worth. Turning to the oldest method of sterilising water, that of submitting it to the action of heat, he thought that looking to his own experiments, water had been sterilised without boiling it. Prof. Wright and himself had found that organisms could be destroyed at a temperature of from between 60 to 70 deg. Cent. With this heat he was satisfied that organisms were destroyed and water was rendered sterile. The plan in use for military purposes generally, and in many civilsed districts—and at Maidstone—had been simply to boil water; and, perhaps, after all, there was no surer, simpler, or better method, if people would only do it, than to simply boil water to sterilise it. But boiling takes time, and people did not always wait for it to boil. Soldiers were specially liable to do this, and drink the water long before it was rendered safe. The lecturer then referred to various systems of the application of heat to water, and said he had no doubt if the practice complied with the theory perfectly, water would thus be rendered

COMPARATIVELY STERILE

and free from danger, but he could not speak with more certainty than this, because, so far as he was concerned, the matter was still *sub judice*. But it appeared as if a want was being met which they had all experienced up to the present time. Of all the questions brought before him for years past, that which had bothered him most had been the purification of suspected water supplies and the difficulty of dealing with them wherever young men, soldiers, troops, &c., are centred throughout the kingdom and scattered abroad, where they would depend upon supplies which were anything but advisable. This question stood almost in the forefront of sanitary knowledge: day by day they noticed the large number of cases of enteric fever, and in London, according to Dr. Shirley Murphy, there was a close relationship between the increase of enteric fever—or its prevalence—and the conditions of the water supply. He hoped that someone who had had practical experience on this very interesting subject would enable them to come to some broad conclusions with regard to it and diffuse useful information.

Discussion ensued, the Rev. F. LAWRENCE, Mr. WOLFF DEFRIES, Dr. RIDEAL, Dr. CHILDS, and the CHAIRMAN taking part.

Professor NOTTER having replied to some of the points raised, a hearty vote of thanks to the lecturer and chairman concluded the proceedings.

At an examination for Inspectors of Nuisances, held at Glasgow on February 4th and 5th, 1898, twelve candidates presented themselves. The following seven candidates were certified, as regards their sanitary knowledge, competent to discharge the duties of Inspectors of Nuisances:—R. P. Fleming, J. Gilfeather, J. Irving, A. Macqueen, J. McClement, A. Smith, Miss A. N. White.

PLUMBERS' WORK AND PUBLIC HEALTH.

THE annual meeting of the Leeds District Council was held at the Mechanics' Institute on Wednesday, 9th February, at which a large number of plumbers, architects, sanitarians, and others, were present.

Dr. CHURTON, who was cordially received, moved: "That this meeting urgently recommends the movement for the National Registration of Plumbers to the notice of all Sanitary Authorities, and of all interested in sanitation, as being calculated to bring about further improvement in the conditions of life amongst our populations; and this meeting further urges the desirability of legislation as needful in order to gain those compulsory powers without which the benefits to be derived from the proper education or examination of plumbers can only be partially realised." He enlarged on the need that existed for educating in the matter of sanitation, not only the plumber, but the people who suffered from sanitary defects, and also the people whose inadvertence or neglect permitted insanitary conditions to exist. It was necessary to compel the attention of these people. As illustrating the need for the diffusion of knowledge for which he pleaded, Dr. Churton cited instances of the effects of sanitary defects that had come within his own knowledge. One was the case of a skilled artisan, who ought, he said, to be a strong, healthy man to-day, but who was a physical wreck because he had lived for fifteen years in an unhealthy house, although he knew when he first became its tenant that the sanitation was defective. Another instance was that of an insanitary house which came under his notice six years ago, and which had been deliberately left in that condition because the agent feared that the landlord would object to the expense of remedying the defect. A third case was that of an office, which the doctor said he had had frequent occasion to visit. Girls were employed as clerks, and though at the outset they had every appearance of enjoying good health, he observed that they were becoming more and more pallid. This circumstance impressed him so strongly that he called the attention of the Sanitary Authorities to the place, with the result that it was discovered that these girls had been working in an atmosphere impregnated with sewer gas. He strongly urged that people who lived in such an atmosphere practically ceased in time to be reasoning beings. The mechanical portion of their intellect alone was left, and it was hopeless to expect them to take the initiative in remedying the evil. There were those who thought that if in this matter they made people too touchy and accustomed them to such fine conditions of living, they would unfit them, say, as soldiers for the rigours of a campaign on the Indian frontier. He was of opinion, he admitted, that we were perhaps overdoing the refinements of life for those who were going to be soldiers, but it was absurd to suppose that by giving them one sort of bad condition we could prepare them for another which was totally unlike it. In conclusion, Dr. Churton referred to the Bill under consideration, and reminded his audience that the privileges which it was proposed to confer upon plumbers would be accompanied by responsibilities. If registered plumbers, as such, were to be granted a virtual monopoly, then a heavy responsibility would attach to those who did work, as he had seen it, so badly that it amounted almost to manslaughter.

Sanitary Inspectors' Associations.

THE NORTH-WESTERN AND MIDLAND.

THE twelfth meeting for the present session of the above Association was held at the Liverpool Royal Institution, Colquitt-street, on Saturday last, the 12th inst.

There was a large number of members present, the President (Dr. Francis Vacher) occupying the chair. Messrs. E. Oakes, Sanitary Inspector, Bolton; W. H. Roby, Chief Sanitary Inspector, Pemberton; and J. Crosby, District Sanitary Inspector, Liverpool, were unanimously elected as members; additional nominations being also received. The transaction of the formal business having been completed, the Chairman called upon Dr. George Reid, County Medical Officer, Stafford, to read his paper on "Sanitary Inspectors and Sewage Disposal."

Dr. REID, who was warmly received, said that it might have been possible to have fixed upon a subject bearing more immediately upon the daily duties of Sanitary Inspectors, but he doubted whether any branch of public health work afforded greater interest in a scientific sense than the problems associated with the efficient disposal of the sewage of towns and villages. Sanitary Inspectors might, moreover, be called upon, and in the future would, no doubt, become more frequently called upon, to act in a detective capacity, in order to keep their respective Authorities informed as to any irregularities taking place in the working of sewage disposal plant, and especially would this be the case in small urban and rural districts. Sewage was a highly putrefactive material containing impurities both in a solid and liquid form. If the solid impurity were removed by any mechanical process, say, by filtration through ordinary filter paper, it was obvious that no actual change was effected beyond the removal of the solid matter, although the result to the eye appeared highly satisfactory.

If the filtrate were kept for a short time, however, the clear fluid became nearly as turbid and offensive looking as the original sample. It was not sufficient, then, to remove from the sewage the solid organic and mineral matter it contained; unless the soluble organic and therefore putrescent material were rendered non-putrefactive, it would in time develope a solid organic *débris* or sludge, which would be deposited in the beds of streams, various putrefactive gases being given off whilst this process was taking place.

It was an undoubted fallacy to suppose that by any chemical process hitherto devised, sewage could be purified to an extent which would meet legal requirements. Chemistry afforded a very valuable and, until recently, possibly, almost an essential step in the process of purification, but no more than a step. The addition of certain chemicals to sewage assisted very materially in the removal of the solid matter, but no chemical hitherto used could effect

the removal, to any material extent, of the organic matter in solution.

The removal of the suspended solids by some process or another was now looked upon as an essential preliminary to further treatment. Crude sewage could not be applied to ordinary artificial filters without at once clogging their pores, and for the same reason application to land was forbidden, unless the available area was very much larger than usually could be acquired.

The conditions essential to successful precipitation by chemical methods having been described, the lecturer passed on to a consideration of the second stage of purification. It was, he pointed out, only within quite recent times that they had any definite knowledge of the process by which dead organic matter was disintegrated. It was supposed that the whole process was a chemical one brought about chiefly by oxidation with the assistance of vegetation. It was known that certain soils had a very powerful purifying effect, provided the sewage was not applied in excess, and so long as short intervals were allowed for aëration. It was believed, however, that after a time the land became "sewage sick," and required a long-continued rest in order to recover itself. Now they knew that this was not the case ; that there was no limit to the length of time land might be continuously in use, provided the quantity of sewage applied to it was not excessive, and that regular and frequent intervals of rest, for aëration only, were allowed. In fact, up to a point the more constant the application of the sewage, the more active the purifying power of the land.

They were indebted to the Massachusetts State Board of Health in the first instance for opening their eyes to the essential principles upou which the artificial filtration of sewage depended. By the elaborate and extensive experiments conducted by that Board, three important facts were established ; first, that the size of the particles composing the filters was all-important ; secondly, that failure would result if a certain comparatively small volume of sewage per yard of filter in a given time were exceeded; and, thirdly, which was the key to the whole question, that the active agent in the process of purification was bacterial life.

It was further known that there were two distinct classes of bacteria engaged in bringing about the disintegration of all dead organic matter—the aërobic and the anaërobic. If sewage were dealt with so that the anaërobic organisms had free scope in attacking it, the change was effected by an unwholesome putrefactive process which polluted the air with foul gases, and the full result could not be attained without the assistance of the aërobic organisms. On the other hand, if the latter organisms were enabled to attack the sewage before the putrefactive organisms had time to proceed very far in their operations, the whole process could be efficiently conducted in a wholesome manner. It mattered not whether the method of disposal was by land or by artificial filtration, success could not be obtained under conditions which were inimical to the life and welfare of aërobic organisms. Suffocate these organisms by depriving them of air, and neither land nor artificial filters would have the slighest effect beyond that of mechanical straining. Other things equal, it followed that the smaller the particles comprising the filter the more perfect the filtration. The subdivision must not, however, be carried too far, for a point would be ultimately reached when the percolation downwards of the sewage took place that water-logging resulted. The material, too, of which the filter was to be composed, was of far greater importance than might be supposed, and although it was not his intention to enter upon a discussion of the comparative merits of different filtering media, they might be interested in hearing a short account of some experimental filters which he had had under observation for more than twelve months. One of these filters was composed of sand and gravel, specially constructed on Lowcock's principle, by which air was continually pumped into the interstices ; another was constructed of coke breeze ; and the third was Garfield's coal filter. These three filters were worked under similar conditions with the same tank effluent—200 gallons per superficial yard being passed through them in twelve hours, and a rest of twelve hours was allowed for aëration.

Dr. Reid exhibited a diagram showing the comparative results attained in the reduction of albuminoid ammonia in the effluent compared with the sewage, the reduction in the amount of oxidisable organic matter, and the amount of nitrification which had been effected, the best results having been obtained by the coal filter, the gravel filter on Lowcock's principle, however, nearly approaching coal in respect to efficiency.

It was difficult to understand at first why coal gave results so greatly superior to coke breeze, and this the more as it had always been supposed that the more porous the material the better its filtering powers. Dr. Barwise, the Medical Officer of Health of Derbyshire, had suggested that the pores of the individual particles of coke retained considerable portions of sewage in a non-aërated state, by virtue of the force of capillary attraction, thus causing putrefactive changes to occur. That this theory contained a great deal of truth there was little doubt, but it not wholly explains the excellence of the coal filter results, for they were not equalled by other non-porous filtering media.

Dr. Reid concluded his address by referring to the two most recent methods which had been suggested as substitutes for chemical precipitation. First, there was the septic tank method, introduced by Mr. Cameron, in which strained sewage was confined in a tank from which the air was excluded. The result was that putrefactive changes took place, which were, of course, brought about by non-aërobic organisms, and the sludge thus disintegrated, leaving a comparatively clear liquid, which, so far as freedom from suspended solids was concerned, might be applied to a fine aërobic filter.

From the first he had looked upon this method with disapproval, notwithstanding the unanimity with which engineers and others hastened to embrace it, because it appeared to him to violate the great principle which had hitherto guided them of keeping the sewage as free as possible from putrefactive changes, previous to its application to land or artificial filters. Up to the present time he had not seen any analytical results from this method of treatment which had caused him to modify his opinion.

The second process consisted in applying crude sewage directly to a large particled filter, and in this case the whole operation was conducted by

aërobic organisms. With intervals for free aëration, the nitrifying organisms which formed in such a filter appeared to have the power of disintegrating even the solid organic matters, as in the case of the finer filters, for dealing with clarified sewage, the process seemed to go on indefinitely, if mineral matter, such as road detritus, were kept back. Of course the effluent from such a filter had to undergo further treatment either by land or finer artificial filtration; but notwithstanding this, the preliminary gain was enormous from an economical point of view.

The discussion was opened by the PRESIDENT, who was followed by Mr. WM. URQUHART (Chairman of Council), Mr. W. BLAND, Dr. MEREDITH YOUNG, and Mr. R. JOHN HUGHES, a hearty vote of thanks being passed to the lecturer at the close.

Dr. REID acknowledged the vote of thanks, and commented in strong terms on the obstructive tactics adopted by the Local Government Board in the past, when dealing with sewage disposal.

THE CLOSING OF ELEMENTARY SCHOOLS IN TIMES OF EPIDEMIC.

MUCH surprise was expressed by many when it was rumoured that the elementary schools of Maidstone were in danger of losing the Government grant through closing their doors during the recent epidemic in obedience to the orders of the Authorities.

We do not think for a moment the Education Department will take such an extreme action. If it does, it will certainly make it very difficult for public officers to take this necessary step of ordering a temporary cessation of school work when zymotic diseases are unusually prevalent in their districts. Naturally members of Councils are inquring what powers they really possess, and for the benefit of all who may not have seen it, we publish below the salient points of a "Memorandum" prepared in the Medical Department of the Local Government Board last summer. It is signed by Dr. Thorne Thorne, who describes it as an attempt to bring together the information in the possession of the Department, as derived from its own Medical Inspectors and Medical Officers of Health respecting school closure and exclusion from school as precautions against infection, with a view to indicate the best means of preventing the spread of disease by school children among their fellows, while avoiding any unnecessary interruption of the work of education.

In the Code of Regulations approved by the Lords of the Committee of Council on Education, the following Article (Art. 88) prescribes, as one of the general conditions required to be fulfilled by a Public Elementary School in order to obtain an annual parliamentary grant, that:—"The managers must at once comply with any notice of the Sanitary Authority of the district in which the school is situated, or any two members thereof, acting on the advice of the Medical Officer of Health, requiring them for a specified time, with a view to preventing the spread of disease, or any danger to health likely to arise from the condition of the school, either to close the school or to exclude any scholars from attendance, but after complying they may appeal to the Department if they consider the notice to be unreasonable."

Article 83 (*a*) prescribes that "if a school has been closed during the year under medical authority, or for any unavoidable cause, a corresponding reduction is made from the number of meetings" (400 a year) required. Article 101 provides that where the Education Department "are satisfied that by reason of a notice of the Sanitary Authority under Article 88, or any provision of an Act of Parliament, requiring the exclusion of certain children, or by reason of the exclusion under medical advice of children from infected houses, the average attendance has been seriously diminished, and that consequently a loss of annual grant would, but for this Article, be incurred, the Department have power to make a special grant not exceeding the amount of such loss in addition to the ordinary grant." Here it will be observed such cases as Maidstone are specially provided for.

The diseases for the prevention of which school closure, or the exclusion of particular children, will be required are principally those which spread by infection directly from person to person, such as diphtheria, scarlet fever, measles, whooping-cough, epidemic influenza, small-pox, and rötheln. More rarely, the same questions arise in connection with enteric fever and diarrhœal diseases, which spread not so much by direct infection from person to person as indirectly through the agency of local conditions, such as infected school privies.

It will be seen that Article 88, quoted above, confers upon Sanitary Authorities an alternative power with respect to public elementary schools. (A) To cause particular scholars to be for a specified time excluded from attendance; or (B) to require the school to be closed for a specified time.

(A) First, as to exclusion from school of particular scholars. Here it will be convenient to consider the circumstances under which the requirements of the public health will be satisfied by the less severe measure of the exclusion from school of particular children. (*a*) It may be laid down as a universal principle that all children suffering from any dangerous infectious disorder (*i.e.*, of a nature dangerous to some of the persons attacked by it, however mild in other cases) should be excluded from school until there is reason to believe that they have ceased to be in an infectious condition (*see* Section 126 of the Public Health Act, 1875).

(*b*) Furthermore, as it is rarely possible to provide effectual separation of the sick from the healthy within the homes of children of the class attending public elementary schools, it must commonly be necessary that all children of an infected household should be excluded from school; first, because otherwise such children might attend school while suffering from the disease in a latent form, or at an unrecognised stage; and, secondly, because it is known that infection may attach itself to, and be conveyed by, the clothes of a person living in an infected atmosphere, even though the person himself remain unaffected. The same considerations will sometimes make it desirable to prohibit the attendance at school of all children from a particular street or hamlet. In the case of infectious diseases involving little or no danger to life, such as mumps or skin diseases, school interests may be more particularly considered. In such case, however, it will usually be well for the Medical Officer of Health to advise the mana-

gers to prohibit the attendace of every child while in an infectious state.

(B) Secondly, as to the closing of schools. This, by more seriously interfering with the educational work of a district, is a much more grave step for a Sanitary Authority to take than to direct the exclusion of particular scholars. It is a measure that seldom ought to be enforced, except under circumstances involving imminent risk of an epidemic, nor even then as a matter of routine nor unless there be a clear prospect of preventing the propagation of disease, such as could not be looked for from less comprehensive action. The mere fact that in an epidemic many of the sufferers are school children does not necessarily show that the disease was caught at school; but the school may with probability be regarded as spreading infection if in a large majority of households attacked the first case be a child attending school; and with still greater probability if a number of children living at a distance from one another, and with no circumstances in common, except that they attend the same school should be simultaneously attacked, and if it can be ascertained that a child or teacher in an infectious state has actually been attending the school.

By Article 18 (6) of the Board's order of 23rd March, 1891, the Medical Officer of Health on the occasion of an outbreak of dangerous infectious disease is to advise the persons competent to act as to the measures to be taken to prevent the extension of the disease. If, therefore, he finds that the children of infected households are attending school he should send notice of the fact to the schoolmaster, and give such advice as appears to him to be necessary with regard to the exclusion of the children from school, and as to the time for which such exclusion should continue. Where the number of children to be excluded is small, and the schoolmaster acts on the advice of the Medical Officer of Health, it may not be necessary to take formal action under Article 88 of the Code; but where the number of children whom it is desirable to exclude from school is such as is likely seriously to diminish the average attendance, or where the advice of the Medical Officer of Health is not followed, and there is danger of the disease spreading by means of the school, notice for the exclusion of the children in question should be made in accordance with the requirements of Article 88.

Several "considerations" are set forth for the benefit of schoolmasters, showing how certain actions of and symptoms in the scholars may indicate the presence of disease among them. In such cases they are urged to at once communicate with the Medical Officer of Health. The length of time that exclusion of individual scholars should be enforced is also dealt with by Dr. Thorn. This should not be decided by any hard-and-fast rule, but the Health Officer should take into full consideration all the surroundings of the case. In some instances it may not be necessary to entirely stop the school work, and the following plan is suggested for deciding the best course to be adopted :—

In deciding whether an outbreak of infectious disease among children of school age may be best combated by closing the school, or whether it will suffice to exclude the children of infected households, the two most important points to be considered are :—(*a*) The completeness and promptness of the information received by the officers of the Sanitary Authority respecting the occurrence of infectious cases. (*b*) The opportunities which exist for intercourse between the children of different households elsewhere than at school.

(*a*) The more prompt and full the knowledge of cases of infectious disease that the Sanitary Authority are able to obtain, the better will be the prospect of checking such disease by keeping away from school the children of infected households, and the less will be the necessity for closing schools. Information obtainable under the Infectious Diseases (Notification) Act, 1889, is especially useful in this direction. If the cases be few in number, and their origin known, the exclusion from school of the children of infected households will probably suffice, but this measure will fail where there are many undiscovered or unrecognised cases, or where the known centres of infection are very numerous. Commonly, the failure of carefully considered measures of exclusion to stay the spread of an epidemic which shows a special incidence upon school children, may be regarded as pointing to the continued attendance at school of children with the prevalent disease in a mild or unrecognised form, and a strong case will appear for the closing of schools. If by reason of the absence or exclusion of a large number of children, the attendance at a school be greatly reduced, it may be found better to close it altogether. This is especially apt to occur in the case of epidemics of measles, a disease which is very infectious in the early stages, before the characteristic rash has appeared, and while the symptoms resemble those of a common cold.

(*b*) The second material consideration, in deciding as to the desirability of closing schools during the prevalence of infectious disease, is the amount of opportunity for intercommunication between the members of different households elsewhere than at school. In sparsely-populated rural districts, where the children of different households, or of separate hamlets, rarely meet except at, or on their way to, the village school, the closing of the school is likely to be effectual in checking the spread of disease. It is less likely to be useful in a town or compact village (particularly where houses are sub-let and yards are in common), where the children of different households when not at school spend their time in playing together, and often run in and out of each other's houses. But it must be remembered that children when at play out of doors are brought into much less close association with each other than when in school. In rural districts, where epidemic diseases are less frequently prevalent, school closing may be required as an exceptional measure to meet an exceptional state of things. As regards more populous places, it must not be forgotten that if schools were to be closed whenever an infectious disease was prevalent, there are many places where schools would hardly ever be open. It will sometimes be necessary to close a school for a day or two to allow of the rectification of sanitary defects of a nature to extend disease, or in order that the school may be disinfected or purified. It has happened that infectious sickness in the master's family has forbidden the attendance of scholars. These more temporary and occasional closures of schools are contemplated in the Education Code, and are to be regarded as having a real importance of their own.

In places where there are several public elementary schools, if an outbreak of infectious disease be confined to the scholars of one particular school, it may be sufficient to close that school only. But where different schools have all appeared to aid in the spread of disease (though perhaps to an unequal extent) the Sanitary Authority may consider it advisable that all should be closed lest children in an infectious state who previously attended the schools that are closed, should be sent to others that might remain open. It must be remembered that Sanitary Authorities have no power in respect of Sunday-schools, or other private schools; except in so far as these may contravene Sec. 91 (5), Sec. 126, or other provision of the Public Health Act, 1875; but it will often be expedient to invite the co-operation of managers of such schools in efforts for securing the public health. Experience shows that they are usually ready to defer to the representations of the Authority responsible for the public health of the district.

The latter part of the last paragraph is important. Granted that as a rule the Committees of Sunday-schools gladly fall in with the request of the Medical Officer, occasionally some may decline to act upon his advice. Therefore to make the step effective, when it is necessary to close the elementary day-schools, the Sunday-schools should also be compulsorily closed, for the self-same children attend in each case.

Institute of Sanitary Engineers

THE CHEMICAL EXAMINATION OF WATER.

By RICHARD HORTON.

(*Continued from page* 150.)

THE process for determining the amounts of free and albuminoid ammonia is not quite so simple as that for chlorine, but, as said before, it presents few difficulties even to those new to chemical experiments. The apparatus required is simple and inexpensive, and is as follows:—A glass retort capable of holding rather more than a litre; it must have a stoppered tubulure. A 24in. condenser, the glass tube being about 34in. by 1in., and a metal body 24in. by 3in. The body must have metal nozzles at either end for cold water supply, and for carrying off the heated water. Six special glass cylinders, with containing marks at 50 cubic centimetres. A half-litre flask. A 25 cubic centimetre burette graduated in tenths of a centimetre. A 2 cubic centimetre pipette. Stands for supporting the retort and condenser. A good Bunsen burner. Half litre of Nessler reagent. A dilute standard solution of ammonium chloride, strength equal to one hundredth of a milligramme of ammonia to each cubic centimetre. An alkaline solution of permanganate of potash. Carbonate of soda. Distilled water, free from ammonia.

All the above can be purchased, excepting the distilled water, which cannot be bought pure enough for the purpose, so the first thing to be done will be to prepare it as follows:—

First clean out the retort with a little strong sulphuric acid, and well rinse with plenty of ordinary tap water; then mount the retort on its stand, and fit the beak of same into the condenser, also mounted on its stand. About three-parts fill the retort with tap water, and arrange with india-rubber tubing for the circulation of a small stream of water inside the outer jacket of condenser; adjust the Bunsen burner so that the retort is well in the flame, taking care that the naked flame is not above the water line in the retort. Upon boiling the water will distil over, carrying with it any ammonia that may be present. Reject the first 250 cubic centimetres of distillate, and then collect about half a litre, the process then being stopped, as it is not advisable to collect more, in case the distillate may again contain ammonia, from destruction of organic matter.

The distillate must be received into a perfectly clean bottle, and the analysis may be commenced by thoroughly cleaning and rinsing the retort as before. The half-litre flask is then filled exactly up to the mark with the sample of water, a small fragment of soda carbonate being added, and carefully poured into the retort, which has been mounted on its stand, and connected with the condenser as before, the apparatus being raised sufficiently to allow the cylinders to receive the distillate.

It is imperative that the distillation should be rapid, and to effect this the retort must be well in the Bunsen flame. There need be no fear of breakage if a good retort be obtained (I get mine from Townson and Mercer), and care taken that the naked flame does not extend above the water line. There must be no support, such as a retort ring, to the bottom of retort.

When the first cylinder is filled exactly up to the 50 cubic centimetres mark it is put carefully on one side for further treatment, and the distillation continued until 150 cubic centimetres more are collected, which may be thrown away, and the process stopped for a time. If the water has been rapidly boiled the whole of the free ammonia will have come over in the 200 cubic centimetres of distillate, but as it has been found that three-fourths of the ammonia invariably come over in the first 50 cubic centimetres collected, the ammonia in that is ascertained, and the total amount calculated from it.

Nessler's reagent has the property of detecting very minute traces of ammonia, and the success of the process depends upon this. If 2 cubic centimetres of Nessler's test are added, by means of the pipette, to the distilled water in the cylinder which was put on one side, and well stirred with a clean glass rod, a yellow to a rich brown coloration will be formed, the depth of tint depending upon the amount of ammonia present. The tint formed in the sample has now to be matched by making up solutions of known strengths of ammonia with the specially distilled water, and adding 2 cubic centimetres of Nessler's test until the desired match is obtained, the tint being judged by placing the cylinders upon a white glazed tile in front of a window, and look down the tubes. In illustration, the following is taken from my note-book:—

Chelsea water, May 29th, 1896.

Free ammonia.—To first 50 cubic centimetres distilled add 2 cubic centimetre Nessler, faint coloration; made up solution with ·5 cubic centimetre standard in ammonia free water, too much; with ·2 cubic centimetre standard, too little; made-up

solution with ·3 cubic centimetre of standard, colour matched; ·3 cubic centimetre of standard equals ·003 milligrammes of ammonia. Therefore the 50 cubic centimetres Nesslerised contained ·003 milligrammes of ammonia, but as this represents three-fourths of the total amount of free ammonia in the sample,

·001 milligrammes must be added

·004 milligrammes in 500 cubic centimetres
2

·008 milligrammes in 1000 cubic centimetres.

The free ammonia is therefore ·008 parts per million.

It is advisable to wait for two or three minutes before making a final observation, as the full tint may not present itself immediately. The ammonia yielded by the destruction of organic matter has now to be considered, and this is effected by adding 50 cubic centimetres of the alkaline solution of permanganate of potash to the remainder of water in the retort, and continuing the distillation until three cylinders have been filled up to their 50 cubic centimetre marks, all of which must be saved for Nesslerising.

Sometimes "bumping" of the contents of the retort may alarm the operator; this may be prevented by gently shaking the retort, or, as I find, by waving the gas flame from side to side. The distillation in this part of the process is slower than that for free ammonia, and needs careful watching throughout. The contents of the cylinders may now be Nesslerised, and the ammonia in each determined in exactly the same manner as for free ammonia.

The following are my notes in the examination for albuminoid ammonia in the same sample of Chelsea water as before:—

Albuminoid ammonia.—To first distillate added 2 cubic centimetres Nessler, strong coloration; made up test solution containing 4 cubic centimetres standard, Nesslerised, not enough; made up test solution containing 4·5 cubic centimetres, colour matched.

To second distillate added 2 cubic centimetres Nessler, made up test solution containing 1·2 cubic centimetres standard, Nesslerised, too much; made up test solution containing 0·9 cubic centimetre standard, not enough; made up solution containing 1·0 cubic centimetre standard, colour matched.

To third distillate added 2 cubic centimetres Nessler, faint coloration; made up test solution containing ·3 cubic centimetres, standard, Nesslerised, not enough; made up solution containing ·5 cubic centimetres standard, not enough; made up solution containing ·6 cubic centimetres standard, colour matched.

	mgs.	
First distillate equalled 4·5 c.c. standard, or	·045	ammonia.
Second distillate equalled 1·0 c.c. standard, or	·010	„
Third distillate equalled ·6 c.c. standard, or	·006	„
	·061 in 500 c.cs.	
	2	
	·122 in 1000 c.cs.	

Albuminoid ammonia in the sample ·122 parts per million.

As the albuminoid ammonia does not come over with the same regularity as the free ammonia, it is necessary to Nesslerise each cylinder, and also occasionally to collect a fourth, if the coloration is more than faint, in the third cylinder.

We have now to consider the interpretation to be put upon the results obtained from the examinations for chlorides, free and albuminoid ammonia, and I do not think a better judgment can be consulted than Professor Wanklyn's. He says in his "Water Analysis," "Deep spring water is often so pure as not to yield 0·01 parts of albuminoid ammonia per million; and unless mixed with surface water, does not yield so much as 0·05 parts of albuminoid ammonia per million." "The filtered water supplied by water companies, no matter whether derived from a lake, from clean mountain streams, or from defiled rivers, yields from 0·05 to 0·10 parts of albuminoid ammonia per million; and, indeed, if the filtration be efficient, approximates to 0·05." "Our general conclusion is that, when the number rises to 0·10, there is defective filtration." And he further states that when the albuminoid ammonia is from 0·10 to 0·20 parts per million, "it is a matter of observation that diarrhœa is frequently prevalent in communities which drink such water." If a water contains no albuminoid ammonia it may be considered as organically pure, although there may be free ammonia and chlorides present, and when the albuminoid ammonia amounts to less than 0·05 it belongs to a good class of water; but, says Professor Wanklyn, "When the albuminoid ammonia amounts to 0·05, then the proportion of free ammonia becomes an element in the calculation; and I should be inclined to regard with some suspicion a water yielding a considerable quantity of free ammonia along with more than ·05 parts of albuminoid ammonia per million." "Free ammonia, however, being absent, or very small, a water should not be condemned unless the albuminoid ammonia reaches something like 0·10 per million." "Albuminoid ammonia above 0·10 per million begins to be a suspicious sign, and over 0·15 it ought to condemn a water absolutely." "Five or ten grains of chlorine per gallon are not a bar to the use of a water, but only a reason for suspicion under certain circumstances." If the amount of chlorine is small, the organic impurity is probably of vegetable origin, and if the amounts of chlorine and free ammonia are large, the presence of decomposing urine seems to be indicated.

(*To be continued.*)

TO OUR READERS.

The Editor solicits the co-operation of readers in making THE SANITARY RECORD *more attractive by means of pen-and-ink sketches, photographs, and diagrams. There are many phases of sanitary work which lend themselves admirably to illustration. By this means not only individual articles, but the journal as a whole will be brightened.*

General News.

HOME.

NOTICE.—On and after 31st March next the Annual Subscription to this Journal will be raised to 12s. 6d. to all NEW Subscribers. NO ADVANCE will be made to our friends whose names are entered on our Subcription list prior to that date, so long as they continue to Subscribe.

HEYWOOD.—The Town Council has decided to appoint a Borough Analyst.

CORNWALL.—An isolation hospital is to be provided, at an estimated total cost of £3600.

SKIPTON.—The Council has under discussion the question of erecting public slaughter-houses.

ASHTON.—The Guardians have agreed to advertise for an architect to prepare the plans for the new hospital.

NORTHFLEET.—A Committee has been appointed to take into consideration the propriety of erecting a public mortuary.

EASTBOURNE.—The Town Council has decided to purchase the Montpellier Baths at £2500, in order to convert them into public baths.

LEIGH-ON-SEA.—The new waterworks of the Urban District Council were opened on Wednesday the 9th inst. The works have cost nearly £14,000.

BIRKENHEAD.—The Town Council has passed a resolution in favour of erecting salt-water baths at the north end of the town, at an estimated cost of £13,000.

ABERDEEN.—It is believed that the slaughter-houses on the Central Park site, which is the one to be recommended to the Council at its next meeting, will cost not less than £30,000.

WESTBURY.—The Local Government Board has sanctioned the application of the Rural District Council to borrow £8000 for works of water supply for the parishes of Westbury and Tilton Marsh.

HEXHAM.—The Urban District Council has decided to purchase from Dr. J. A Jackson, three-fourths of an acre of land situate in Haugh-lane, at the price of £300 for the erection of slaughter-houses.

BATTERSEA.—The Vestry has resolved to apply to the Local Government Board for sanction to the borrowing of the sum of £25,000 for the erection of the new public baths and wash-houses in Battersea Park-road.

STOURBRIDGE.—A Local Government Board inquiry has been held relative to the application of the Urban Council for compulsory powers for the purchase of a site for a refuse destructor near to the sewage pumping station.

RUSKINGTON.—The Local Government Board has found, as the result of an inquiry held in November on the petition of the Earl of Winchilsea, Captain Cragg, and others, that the Ruskington Urban District Council is in default with regard to providing a proper water supply, and that such a supply can be obtained. The Council is directed to procure such a supply within three months, and is ordered to pay the costs. The petitioners have thus fully proved their case.

HASTINGS.—A Local Government Board inquiry has been held into the application of the Corporation for sanction to borrow £139,000 for a new water scheme to be carried out in the Brede Valley.

UPHOLLAND. — A Local Government Board inquiry was held recently as to an application of the District Council for powers to borrow a further sum of £4000 for extension of the waterworks, purchase of land, and other expenses for waterworks purposes.

LEEDS.—The epidemic of scarlet fever shows little, if any, signs of abatement. There is no apparent diminution in the number of cases reported from day to day, 50 new patients having been conveyed to the fever hospital last week, as against 47 in the previous week.

MIDDLESBROUGH. — Small-pox continues to spread despite the energy which has been displayed by the Authorities in their efforts to stamp it out. So serious and alarming has the outbreak become, that bills have been freely distributed about the town advising people to be at once re-vaccinated.

GOOLE. — The Local Government Board has approved of the plans for the proposed new lavatories at the infirmary and extensive alterations to the laundry and wash-house at the Goole Union workhouse. The plans and specifications have been prepared by Mr. E. C. Buchanan Tudor, C.E., the Board's architect and surveyor.

COVENTRY.—At the last meeting of the City Council the Medical Officer of Health (Dr. E. Hugh Snell) reported that the principal figures relating to the vital statistics of the city for 1897 were as follows: Estimated population, 61,234; recorded death-rate, 16·8; average death-rate for previous ten years, 17·5; zymotic death-rate, 1·8; average ditto for previous ten years, 1·6.

MIDDLESBROUGH.—Owing to the epidemic of small-pox it has been decided to close the Lending Department of the Free Libraries and the Lending Library of the Literary and Philosophical Society. The Public Vaccinator has been ordered to make a house-to-house visitation to vaccinate the inhabitants free of charge, for which purpose the services of three doctors have been retained.

HOPE.—The directors of the Castleton Water Company have expressed their willingness to supply the village of Hope from their reservoirs on Losehill on terms to be agreed upon, and the District Council has approved of the arrangement. The engineers, Messrs. Sterling and Swann, of Chapel-en-le-Frith, consider the scheme is quite practicable, and it is probable negotiations will be entered into instead of an expensive scheme being carried out at Hope.

MORPETH.—At a recent meeting of the County Council of Northumberland the report of the Committee of Visitors regarding the proposed water supply to the County Asylum at Morpeth was unanimously adopted. The scheme provides for the conveying of water in a 6in. main from a spring at Doe Hill in the Witton Shields district to the Asylum, a distance of over seven miles. The water has been examined bacteriologically and chemically, and found to be of excellent quality. The scheme has been designed by Messrs. D. Balfour and Son, civil engineers, Newcastle, who will shortly advertise for tenders for the work.

GREAT HUCKLOW.—The Local Government Board has deferred its decision with reference to the application of the District Council for sanction to borrow £400 for works of water supply for Great Hucklow, as it would be desirable to include Great Hucklow in one of the groups to be supplied from the Camp Hill spring.

ABROAD.

NAIHATI.—The Naihati Municipality has under consideration the necessity of opening waterworks before long.

DINDIGUL.—The Dindigul Municipality has applied for a loan for the extension of the water-supply works.

HOWRAH.—The Bengal Government has sanctioned a loan of 40,000 rupees to the Howrah Municipality for extending their waterworks.

WINNEPEG.—Black diphtheria has broken out among the workmen on the Crow's Nest Railway. Several deaths and a number of new cases are reported. Owing to the mountainous nature of the region it is difficult to make proper provision for treating the disease.

Personal.

DR. SLADE KING has been reappointed Medical Officer for the Dulverton rural district.

MR. S. P. FRYER has been appointed Inspector of Nuisances for the rural district of Hastings.

MR. J. B. O. RICHARDS has been appointed Medical Officer for the Swinhope district of Caiston union.

MR. F. J. FROST has been appointed Medical Officer for the Llanhilleth district of Pontypool union.

MR. C. N. THOMAS has been appointed Medical Officer of the Sydney district of Chepstow union.

MR. E. J. WILSON has been appointed Inspector of Nuisances for the rural district of North Witchford.

DR. WALKER has resigned the position of Medical Officer to the Beverley union on account of continued ill-health.

THE Local Government Board has sanctioned the appointment of Dr. M. Gepp as Medical Officer of Health for Dawley.

DR. J. J. CLARKE has been appointed Medical Officer of Health for Walthamstow in room of Dr. St. Clair Shadwell, resigned.

MR. JOHN ALEXANDER BRODIE, a member of the firm of Wood and Brodie, engineers, has been appointed City Engineer for Liverpool, at a salary of £1000 per annum.

MR. CHAS. MASON, A.M.I.C.E., has resigned his Surveyorship to the Vestry of St. Martin-in-the-Fields, having accepted a partnership in the old-established business of Messrs. Foster and Pearson, heating engineers, &c., of Beeston. His resignation has been accepted with much regret, he having held the appointment for the past eight years.

Sewerage Schemes.

[To MUNICIPAL ENGINEERS AND SURVEYORS.—The Editor will be pleased to receive items for publication relating to sewerage schemes projected or inaugurated, together with explanatory diagrams or photographs. The former should be drawn and lettered in black ink.]

A SPECIAL Committee has been appointed to deal with the West Hartlepool sewerage scheme.

THE Stowmarket Urban District Council has approved of the plans and estimates of the sewerage scheme, and will apply to the Local Government Board for a further loan of £5000.

THE Local Government Board have recommended the Public Works Loan Commissioners to lend £6088 to the Wombwell Council for the Wombwell and Hemingfield sewerage.

THE Local Government Board has sanctioned the Bucknall sewerage scheme of the Stoke Rural District Council, and the contractors will be ready to commence the work by the end of the month.

A LOCAL Government Board inquiry has been held relative to an application by the Rural District Council of Yeovil for sanction to borrow £1600 for purposes of sewerage and sewage disposal for the parish of Montacute.

THE Rural District Council of Uxbridge has consented to the expenditure and borrowing of the sum of £13,000 for the purpose of carrying out schemes of sewerage and sewage disposal for Eastcote and Northwood, in the parish or contributory place of Ruislip.

THE Hexham Urban District Council has decided to purchase from Mr. Wm. Ridley, the piece of land next his manure works, at 3s. 6d. per square yard, the estimated area required being 1500 square yards. This land is required for the septic tank system of sewage disposal.

AT the last monthly meeting of the Bolsover Urban District Council, the Engineer, Mr. Wagstaff, who was engaged to prepare a scheme showing the best method for sewage disposal at Bolsover, gave a descriptive report. He estimated the scheme would cost £2000, exclusive of the cost of land, &c. The report was deferred for further consideration.

A LOCAL Government Board inquiry has been held at Armagh into the applications of the Commissioners to be empowered to put into force the provisions of the Land Clauses Act for the purpose of enabling them to acquire, otherwise than by agreement, the lands in the townland of Drumcarn and Corporation, upon which it has been decided to construct the new disposal works, and to obtain the sanction of the Local Government Board to their borrowing a sum of £12,000 to enable them to provide the new scheme.

THE Local Government Board has given its sanction to the Honley Council borrowing £6028 for the purposes of the drainage of the district and part of the sum required for the outfall sewer and sewage disposal, which, however, does not include the drainage of Deanhouse and Oldfield, nor certain street improvements, for which further application will have to be made.

ON Tuesday afternoon, the 8th inst., the sewage works, which had been in course of construction by the Midsomer Norton Urban District Council at Welton, for treatment ot sewage for Midsomer Norton before flowing into the river Somer, were officially opened. The cost of the works has been about £2100. At the conclusion of the tour of inspection the chairman of the Urban District Council (Mr. G. Carter) expressed satisfaction at what he had seen, and said their engineer was to be congratulated on the way in which he had carried out the work.

AT a special meeting of the Newmarket Urban District Council held recently, Mr. Frederick Beesley, Engineer of the new main drainage scheme, read his estimate of the cost of the work, which was as follows: — The whole of the sewers, £24,203 14s. 3d.; manholes, £2220; deep manholes, £315; gullies, £100; ventilating columns, £250; bacteria tank system, £2836; automatic flushing tanks (six), £300; laying out and draining seventeen acres of land, £1500; railway crossing, £750 5s. 9d.; connecting house drainage, £2000; total £34,475. This was £6000 more than the original estimate; but the cost of material had risen from 5 to 10 per cent., the drain was to be laid deeper on Exning-road, and that, with the additional surface drains, &c., would account for over £5000 more. The other expenses he estimated as follows:—Land, £2000; Engineer's charges (5 per cent. on cost of work), £1750; Clerk of Works, £250; easements, £783; legal expenses and sundries, £767; total, £5500. It was resolved that powers to borrow £45,000 be immediately sought.

A SPECIAL meeting was held at Underwood recently for the purpose of laying before the ratepayers the proposed sewerage scheme. Mr. E. Briggs referred to the steps taken in the matter, and remarked that they had a loan standing against them of about £15,000 for the water scheme, and he thought if the proposed sewerage scheme was carried out it would mean another £15,000, which he considered would be more than they could undertake with a rateable value of only £20,000. The District Council had had plans got out, the carrying out of which it was estimated would cost something like £7000. As the result of negotiations with the Local Government Board it had now been ascertained that they could borrow money for such parts as required doing first, leaving the other sections to be subsequently completed. Finally, a resolution was adopted to the effect that the District Council use its best endeavours with the Local Government Board to have such portion of the sewerage works carried out as require doing first, and that the whole scheme be spread over as long a period as possible, the money to be borrowed from time to time as required.

THE Coventry City Council has adopted the report of the General Works Committee recommending the acceptance of H. Weldon's (Birmingham) tender of £39,734 14s. 7d. for the execution of the first portion of the works necessary for carrying out the Lodge Farm sewerage scheme, plans and specifications for which have been prepared by Mr. Mansergh. The tender is within Mr. Mansergh's estimate, and includes sewers, rising mains, tanks, and work on farm.

Lighting.

THE Skipton Council has under discussion the proposals for purchasing the plant of the Skipton Gas Company.

THE Derby Town Council have resolved to expend £126 for converting gas lamps and fittings into incandescent electric light lamps, and £346 for wiring.

THE Birmingham Gas Committee's report recommending the extension of the gasworks, at an estimated cost of £366,000, has been approved by the City Council.

A LOCAL Government Board inquiry has been held into the application of the Bramall Parish Council to borrow £500 for the purpose of lighting the North and South Wards of the parish.

THE Taunton Town Council has decided that application be made to the Local Government Board for sanction to the borrowing of £10,000 for purposes of electric lighting in the borough.

THE Urban District Council of Kettering has decided to defer the further consideration of the electric lighting of the town for a period of three months, when the new Council will be in office.

IT has been decided to adopt the electric light in St. Mary Church. The cost of the installation is estimated at £300, towards which donations to the amount of £100 have already been promised.

A MEETING of the Troon Commissioners was held recently for executing the Burghs Gas Supply Act. It was agreed that notice be given to the Troon Gas Light Company that the Commissioners are willing to buy or to treat for the purchase of the undertaking of the company, and that the Gas Company give notice before two months.

A STEADY organised agitation is being carried on in Barking against the electric light scheme. A committee has been formed advocating the adoption of a particular form of incandescent gas lighting, and literature on the subject is being freely distributed. Ratepayers are being invited to sign a petition against the electric light proposals.

Correspondence.

We do not in any way hold ourselves responsible for opinions expressed by our correspondents.

RELATIVE COST OF WORKS OF SEWAGE DISPOSAL.

(*To the Editor of* THE SANITARY RECORD.)

SIR,—In the second "Note" in your issue of the 4th inst. (page 105), it is stated that this question has not received the attention which it deserves; and we are invited to furnish figures which will enable Local Authorities to form an opinion on the subject. We need hardly point out that it is impossible to lay down any scale of cost which will be generally applicable, under the widely different circumstances which are met with in different places. Inasmuch, however, as your note is calculated to give the impression that our process is more expensive than that in use at Sutton, which impression is altogether incorrect, it may be well to quote a specific case in which very careful estimates have been prepared.

The works at Exeter have been designed to deal with the sewage of 47,000 people, the maximum flow provided for being 2,500,000 gallons per day. They are estimated to cost £13,940, including grit chambers, conduits to tanks and from tanks to filters, penstocks, &c., but exclusive of engineering charges. The cost is, of course, greater than for a place of the same size sewered on the separate system, in which not only would the size of the works be smaller, but no provision for removing road grit would be necessary.

It is assumed in your note that "under the Exeter system the cost of construction of tanks must be somewhat heavy, and being a patented process, royalties will be payable to the patentees." In this installation, however, not only is the cost of the tanks not heavy as compared with that of the filters, but it is actually only one-half of the latter amount. In the Sutton process two sets of filters are used, while in ours one set is replaced by the tanks, thus saving one-half the cost of one set of filters, to say nothing of the saving in cost of land. No royalty is included in the sum quoted above; but we may state that the royalty that we should charge in such a case would not bring the cost of our works up to that of works on the Sutton system.

In the Exeter works artificial walls are provided between the filters; but in any case where the site admits of these being dispensed with under the Sutton system they could equally well be done without under ours. Although the walls and floors do not represent by any means the heaviest part of the cost of filters, their omission would reduce to some extent the excess of this item over the cost of the tanks. Against this must be set the possibility of reducing the cost of the tanks under other circumstances; for instance, these now under consideration are larger than they would be in some cases for the same population. The fall required is often an important factor in the cost of works. The Exeter system requires only one-half the fall necessary for the Sutton system.

Hitherto we have dealt only with the question of first cost, which, as Sanitary Authorities have found by painful experience, is often the least formidable part of the burden entailed by sewage works. When we come to the cost of working, the advantage of the Exeter is still more marked. In the first place, the tanks deal with the sewage without preliminary screening, thus saving the cost of clearing the screens and disposing of the intercepted matters; secondly, they do not require the periodical trenching which is necessary for the coarse bacteria bed; thirdly, the automatic alternating gear saves the labour which would otherwise be required to work the filters, and, what is of greater importance, prevents the temporary losses of their purifying power which negligence on the part of the attendants is liable to bring about. If the annual saving which our system effects, even as compared with that of Sutton, is capitalised, we venture to think it will dispel any doubt which might otherwise exist as to the relative cost of the two systems.—Yours faithfully,

CAMERON, COMMIN, AND MARTIN.

7 and 8, Bedford-circus, Exeter,
8th February, 1898.

Law Cases.

INCANDESCENT INFRINGEMENT.

LAST week in the High Court, before Justice GORELL BARNES, sitting as an additional judge in the Chancery Division, Mr. A. J. WALTER moved, in the matter of the Incandescent Gas Light Company, Limited, *v.* Seligman, for judgment in default of defence, the action being one for infringement of letters patent held by the plaintiff company. Plaintiffs claimed the usual relief, an injunction to restrain, and also damages and costs. The particular act of infringement charged was a sale at 17, Union Passage, Birmingham, of mantles constructed in infringement of plaintiffs' patent. The defence, it was stated, had been struck out.

His LORDSHIP granted the order applied for.

IMPROPER FLUSHING APPARATUS.

EDWIN SHARLAND, Ambro House, Cheltenham, was charged, under the Public Health Act, with neglecting to comply with a requirement of the Sanitary Authority, to provide proper flushing apparatus in his premises.

The Town Clerk (Mr. E. T. Brydges) prosecuted.

Albert Edward Hudson, Sanitary Inspector, deposed that the defendant had not put up the flushing apparatus since the case was last before the magistrates.

Mr. Brydges said defendant could well afford to do the necessary work. The maximum fine under the Act was £5, with a daily penalty not exceeding £2 until the work was carried out.

A fine of £1 was imposed, with a daily penalty of 2s. 6d. to commence fourteen days from that day, until the work should be completed to the satisfaction of the Medical Officer. Costs, 10s., went with the sentence.

Notes and Queries.

[Subscribers have the privilege of obtaining advice in this column on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed to THE EDITOR, "Notes and Queries," THE SANITARY RECORD, 5, Fetter-lane, London, E.C.]

NOTE.—If an answer be required immediately, a stamped addressed envelope must be enclosed, when we will endeavour to furnish a copy of the answer by post, as owing to the large number of queries received we cannot guarantee the insertion of a reply in the succeeding issue.

964.—DIPLOMA FOR SANITARY SCIENCE.—"J. E." writes:—"I shall be glad if you will oblige me with information as to the steps to take to get the diploma for Sanitary Science."

Answer.—If our correspondent wishes to obtain the diploma in Practical Sanitary Science, which is granted after examination by the Sanitary Institute, he should procure and study the following books, viz.:—Reid's "Practical Sanitation," price 6s.; Balfour Stewart's "Lessons in Elementary Physics," price 4s. 6d.; Roscoe's "Chemistry;" Macmillan's "Science Primers," price 1s.; Geikie's "Geology;" Macmillan's "Science Primers," price 1s.; Rideal's "Water and its Purification," price 6s.; Allen's "Building Construction," price 12s. 6d.; Buchan's "Plumbing," price 3s. 6d.; Vacher's "Healthy Homes," 2s. 6d.; Spinks' "House Drainage Manual," price 5s.; Maxwell's "Ventilation, Lighting, and Heating," price 2s.; also "Model Answers to Examinations for Sanitary Inspectors," price 2s. Any of the books named may be obtained from the Sanitary Publishing Company on receipt of the published price.

965.—PUMPS: BOOKS ON RECOMMENDED.—"J. E." writes:—"Could you tell me of some inexpensive book on the construction and principles of working of ordinary pumps, such as are generally used in rural districts for drawing water from wells from 6ft. to 40ft. deep?"

Answer.—Either of the following books will be found to serve the purpose required by our correspondent, viz.:—(1) "The Pump Fitters' Guide: For Calculating and Fixing Pumps," by John Eldridge, price 1s.; (2) "Pumps: A Practical Handbook on Pump Construction," by Philip R. Björling, price 5s. Copies may be had from the Sanitary Publishing Company on receipt of the published price.

966.—NEW SYSTEM OF SEWERAGE: CONNECTION OF HOUSE DRAINS.—"R. R." writes:—"There has been a new system of drainage carried out in our town recently, and the Drainage Committee of the Corporation are making charges to owners of property for connections to new sewers, and also for interceptor and chamber in the public roadway. Formerly the drains from these houses emptied into the canal upon which they abutted. Have the Authorities the power to compel payment for this work? To my mind the canal was to all intents and purposes a common sewer. Am I right?"

Answer.—Whether the canal into which the houses drained was a sewer would be a question of fact for the decision of the magistrates. With the information before us we are unable to advise. Are the Local Authority carrying out the connection of the houses to the new sewer by agreement under which the owner undertakes to pay the prescribed amount? Or have they served statutory notices upon the owners under Sec. 23 of the Public Health Act, 1875, to provide sufficient drains and connect them with the sewers, and on the owner's default the Authority are doing the work? If a copy of the notice (if any) which has been served were furnished us we should be better able to advise.

967.—DISINFECTION OF HOUSES: RE-PAPERING OF WALLS.—"Variola" writes:—"The Infectious Disease (Prevention) Act is in force in this town, and I am in the habit of issuing a notice to the owners of houses in which there has been infectious disease to re-paper and whitewash walls and ceilings respectively, and the work has been carried out. What power has the Medical Officer of Health to legally enforce these notices? Can it be done under Sec. 5 of the above Act, in which the words 'cleansing and disinfecting' are constantly used? I know the re-papering is insisted upon in several towns, but I am informed the Corporation in these towns allows about 5s. per room for the material, the owner finding all labour. My argument would be that re-papering and whitewashing, together with stripping off the paper, is a necessary part of the disinfection and cleansing, but I should like your opinion as to whether this argument would be likely to stand. I cannot find any cases on the subject, and would feel very grateful for any information you can give."

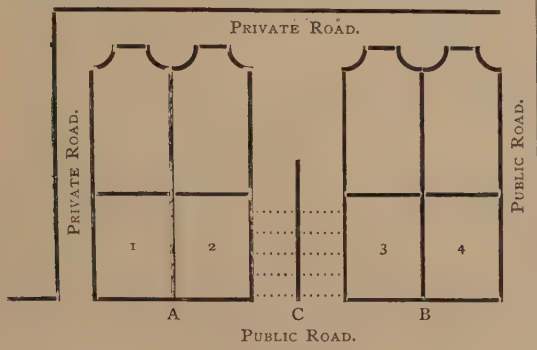
Answer.—In our answer to a similar Query 845, in our issue of November 5th last, which had reference to proceedings under Sec. 120 of the Public Health Act, 1875, we expressed a doubt as to whether a Local Authority could enforce a notice requiring the walls of a room to be re-papered after a case of infectious disease, and we were influenced in forming our opinion by Sec. 121 of the Act, which provides that "any Local Authority may direct the destruction of any bedding, clothing, or other articles which have been exposed to infection from any dangerous infectious disorder, and may give compensation for the same." It may be noted that the corresponding provisions in Secs. 5 and 6 of the Infectious Disease (Prevention) Act, 1890, differ considerably from Secs. 120 and 121 of the Act of 1875, and we do not think the same objection could be raised in enforcing notices for the destruction of wall paper under the later Act as under the earlier one. We do not know of any decided case bearing directly on the point. The practice of requiring the walls to be cleansed by the removal of paper is one which is required by a large number of Authorities, and we think, in case of proceedings for the recovery of expenses, under Sec. 5 (2) of the Act of 1890, that magistrates would be influenced by the evidence of the Medical Officer of Health (which should be offered) that the stripping of the walls and re-papering was a necessary act for the efficient cleansing and disinfection of the room or rooms, and that expenses so incurred would be reasonable.

968.—BUILDING BYE-LAWS: AUTHORITY IN DEFAULT: APPEAL TO LOCAL GOVERNMENT BOARD.—"Z." writes:—"What means are there of making a Sanitary Authority enforce its bye-laws? A certain borough having bye-laws and a surveyor allows houses to be built without proper foundations or damp-proof course. Stoneware drains are allowed to be laid under houses without concrete, and no test for soundness is applied, and other matters contrary to the Public Health Acts are permitted to be done. The ratepayers are remiss on the subject, and will not elect councillors pledged to enforce the bye-laws. Would an appeal to the Local Government Board be of any service?"

Answer.—Under the circumstances named we are of opinion that the most effective way to secure observance of the bye-laws would be to make a complaint to the Local Government Board under Sec. 299 of the Public Health Act, 1875, that the Local Authority has made default in enforcing the provisions of the Public Health Act and Bye-laws made thereunder. The complaint may come from any person. It should be in writing upon folio foolscap paper, addressed to the President of the Local Government Board, under cover addressed to the Secretary, and should state with as much conciseness as practicable the facts of the case which show the default of the Authority, and should offer proof of the complaint. The complainant would do well to be provided with evidence from a number of persons, and whose evidence could be thoroughly relied on. The Board upon receipt of the

complaint will probably communicate it to the Local Authority for their observations and explanations. If no redress is obtained, and the Board deem the matter of sufficient importance to require further proceedings, they may cause an inquiry to be held by one of their Inspectors, when evidence will require to be tendered before him in support of the complaints. If the facts be as stated by our correspondent, complaint to the Local Government Board is most desirable.

969.—Building Bye-laws: Power to Disapprove Plans.—"W. C." writes:—"Will you kindly inform me whether a Local Authority would have power to refuse to allow a building to be erected under the following circumstances? The Model Bye-laws are in force:—



A and B are two blocks of houses which formerly belonged to two owners. They now belong to one owner, who wishes to utilise the open space C between the buildings by constructing a shop and two bedrooms over, for the use of, and to be thrown into, No. 2 house. The open space at present is occupied by steps, which lead to the basement of the buildings, but these are never used, as there are entrances in the fronts. There are no windows abutting."

Answer.—The block plan sent is not sufficient for us to properly advise. A copy of the deposited plans would have assisted us. We are unable to tell from the plan what area of the site is to be covered with the proposed building, and whether the required open space at the rear will be provided. Assuming, however, that the specified open space can be provided, and that the other requirements of the bye-laws as to thickness of walls, drainage, &c., are complied with, the Local Authority will not be enabled to prevent the owner from erecting the proposed building.

970—Inspectors' Examination of Sanitary Institute: Books Required.—"J. H." writes:—"I am intending to sit for Sanitary Inspectors' examination. Will you kindly inform me what books I shall require, and the prices of same?"

Answer.—The following books are recommended, viz.:—Reid's "Practical Sanitation," price 6s.; Buchan's "Plumbing," price 3s. 6d.; Spinks' "House Drainage Manual," price 5s.; "Model Answers to Questions set at the Inspectors' Examination of the Sanitary Institute," price 2s.; Vacher's "Food Inspector's Handbook," price 2s. 6d.; and Vacher's "Healthy Home," price 2s. 6d. All the books are obtainable post free from the Sanitary Publishing Company. As we have previously pointed out in these columns, candidates for Sanitary Inspectors' examinations are much more likely to obtain success by placing themselves under the tuition of a good professional "coach"—several of whom advertise in our pages—than by indiscriminate and unaided study.

971.—Bacteria Tanks: Mode of Construction.—"A. K. B." writes:—"I am much obliged for your reply to my Query 951 in your issue of the 4th inst., but there is a special question with reference to bacteria filters for private houses, which is, that, inasmuch as the sewage flow from them is very intermittent and irregular in quantity, I have been recommended to construct a filter 3 yards square by 4ft. deep, but this might get filled in three hours or it might take three days. There is, of course, no difficulty in arranging for the overflow going into another filter, either with or without automatic arrangements. But the point is, will this irregularity injure the efficacy of the filter? Do the bacteria work when the filter is full or when it is empty, and are they liable to be drowned by a prolonged immersion during slow filling? Also is the same time for aëration required after a quick as a slow filling?"

Answer.—As we pointed out in our former reply, it is advisable to construct the filters in duplicate. They should, moreover, be so arranged that the flow into a tank should not be continuous for a longer period than 12 hours. The intermittency of application of the sewage is requisite in order that the bacteria may attack the sewage when in contact with the filter, and that they may also obtain the requisite supply of oxygen when the filter is emptied. A prolonged period of filling will probably be found to necessitate a proportionately longer rest period than when the conditions are reversed. Automatic discharge of the filter can be provided by the construction of a syphon in a chamber having direct connection with the filter, and this may often be found advantageous. We will endeavour to advise further if required.

Contracts Open.

The dates given below are the latest up to which tenders can be received.

Bury (Lancs), February 21st.—Sewer.—Mr. J. Cartwright, borough engineer.

Dover, February 22nd.—Sewers.—Mr. Henry E. Stilgoe, A.M.I.C.E., Town Hall, Dover.

Hunslet (near Leeds), February 28th.—Sewerage Works.—Mr. Sam Shaw, C.E., Dewsbury.

Basford (Notts).—February 21st.—Sewerage Works.—Mr. Herbert Walker, Newcastle-chambers, Nottingham.

Burnley.—February 21st.—Scavenging.—The Sanitary Inspector's Office, Yorkshire-street, Burnley.

Newton-in-Makerfield.—February 21st.—Sewers.—Mr. Richard Brierley, engineer and surveyor, Town Hall, Earlestown.

Wigston Magna (Leics).—February 21st.—Scavenging, &c.—Mr. W. G. J. Clark, sanitary inspector to the Council, 32, Bell-street, Wigston Magna.

Rathdown (Ireland). February 23rd.—Drainage.—The Registrar's Office, Dean's Grange Cemetery.

St. Austell (Cornwall).—February 23rd.—Drain Pipes.—Mr. M. Spear, highway surveyor, St. Austell.

Denton (Lancs).—February 24th.—Sewer.—Mr. G. H. Newton, surveyor, Market-place, Denton.

Eccles (Lancs).—February 24th.—Sewerage Works.—The Borough Engineer, Town Hall, Eccles.

Llangyfelach (Wales).—February 28th.—Removal of Refuse.—Mr. G. B. Haynes, clerk, 8, Fisher-street, Swansea.

Ripon.—February 28th.—Sewers, &c.—Mr. H. A. Johnson, civil engineer, 14, The Exchange, Bradford.

King's Lynn.—March 2nd.—Sewers.—Mr. E. J. Silcock, C.E., borough engineer, King's Lynn.

Litherland (Lancs).—March 2nd.—Removal of Nightsoil.—Mr. W. B. Garton, surveyor, Public Offices, Sefton-road, Litherland.

Oldham.—March 2nd.—Sewers, &c.—Mr. S. A. Pickering, A.M.I.C.E., borough surveyor, Oldham.

Vacancies.

ASSISTANT SUPERINTENDENT OF SEWAGE WORKS (LONDON, N.W., February 22nd).—For the Willesden Urban District Council. Salary, £2 per week with residence. Mr. O. Claude Robson, engineer, Public Offices, Dyne-road, Kilburn, N.W.

CLERK OF WORKS (SOUTHAMPTON, February 19th). For the Southampton Harbour Board. Salary, £3 3s. per week. Mr. A. H. Skelton, clerk, Harbour Offices, Town Quay, Southampton.

INSPECTOR OF NUISANCES, &c. (MILFORD HAVEN, February 19th).—For the Urban District Council. Salary, £60 per annum. Mr. Thomas H. Lewis, clerk, Council Office, Milford Haven.

SANITARY INSPECTOR (LONDON, W.C. (March 8th). For the Holborn Board of Works. Salary, £120 per annum. Mr. Matthew H. Hale, clerk, Holborn Town Hall, Gray's-inn-road, W.C.

SURVEYOR (LONDON, W., March 7th).—For the Vestry of St. Marylebone. Salary, £600 per annum. Vestry Clerk, Court House, Marylebone-lane, Oxford-street West.

SURVEYOR, &c. (MASHAM, YORKS, February 26th).—For the Urban District Council and Urban Sanitary Authority. Salary, £50 per annum as Surveyor, £25 per annum as Inspector, and £15 per annum as Collector. Mr. John H. Calvert, clerk, Masham, R.S.O., Yorks.

SURVEYOR, &c. (MAYBOLE, SCOTLAND, February 21st).—For the Maybole Burgh Commissioners. Salary, £120. Mr. James Gibson, solicitor, Maybole, Clerk to the Commissioners.

SURVEYOR'S ASSISTANT (BURTON-UPON-TRENT, February 19th.)—For the Corporation. Salary, £120 per annum. Mr. George T. Lynam, borough surveyor, Town Hall, Burton-upon-Trent.

COMPETITIONS.

WINCHESTER, February 28th.—Public Baths.—Full particulars, with plan of site, to be obtained on deposit of £1 1s. on application to the City Surveyor, Guildhall, Winchester, which will be returned on receipt of a *bonâ fide* set of plans. Premiums of £25 and £15 will be awarded for the designs adjudged by the Council of sufficient merit, and placed first and second in order respectively. Drawing and detailed estimate to be deposited at the office of Mr. Walter Bailey, town clerk, Guildhall, Winchester.

To Surveyors, Sanitary Inspectors, &c.—First-class Cycles at reasonable prices. Don't place your orders elsewhere until you have seen our post-free catalogue.—MELROSE CYCLE COMPANY, Coventr

THE

Sanitary Record,

FEBRUARY 25, 1898.

SEWER VENTILATION AND ITS ATTAINMENT.

An important conference of metropolitan Surveyors and Medical Officers of Health has been convened by the London County Council for this day (Friday), to consider the question of sewer ventilation. It is to be hoped that some practicable means may be suggested to reduce this crying evil, the continuance of which is a discredit to Sanitary Authorities and their officials. The subject was one which came up for discussion at the meeting of the Incorporated Association of Municipal and County Engineers held at the Institution of Civil Engineers on Friday last, with a view to an agreement being arrived at amongst metropolitan surveyors, but there appeared to be such a divergence of opinions amongst them as to remedies to be suggested at the conference that in so far as surveyors are concerned we doubt whether any good will come of it.

It was suggested at the meeting referred to that the difficulties in regard to sewer ventilation had been brought about by the inability to ventilate sewers by means of house drains and the provision of disconnecting traps on house drains, and it was urged by some speakers that this system had been brought about owing to the theories of Medical Officers of Health.

We have no desire to bepraise the services of one class of municipal official over that of another, but on the subject of sewer ventilation and in protecting the health of householders, we are bound to admit that the Medical Officer has shown himself superior to the surveyor. We would go even further than this, and state that, in our opinion, the remedy for reducing the sewer gas nuisance is more a question for chemists and Medical Officers of Health than for surveyors. The discussion at the meeting referred to resulted in two propositions being submitted : — (1) That the ventilation of sewers should be carried out by increasing the number of open gratings in the surface of roads; and (2) that as an aid to the ventilation of sewers dwelling-house owners should be required to carry up ventilating shafts by a connection with the house drain on the sewer side of the disconnecting trap.

Neither of these proposals, we think, reflect to the prestige of engineers, but both are, in our opinion, impracticable of attainment. The free ventilation of sewers is an old theory, and has been tried long ago and abandoned. True, if it were possible to construct sewers in the form of open channels or culverts, and protected if necessary by continuous gratings, the offensiveness of fresh sewage would be small at or near the heads of sewers; but sewage quickly decomposes, and while those living in the upper district of a town would discharge their sewage quickly and at little nuisance to themselves, those living in the lower parts would have to suffer from the decomposing sewage sent down past them. The fallacy of the open sewer argument is well shown in regard to some of our rivers, such as the river Aire at Leeds, and many others we could name, which receive volumes of sewage, but which are positively dangerous to health from the filthy odours given off from their surface. And if this be the case in open streams where the sewage is largely diluted by fresh water, what would be the case in regard to open streams of undiluted sewage?

The second proposal as to ventilating the sewers by means of shafts contiguous to houses, and laid at the cost of owners of property, is also, we fear, an equally impracticable proposal. In the first place, Local Authorities are required by statute to ventilate their sewers and maintain them so as not to be a nuisance. Ventilation of sewers should, we maintain, be effected in themselves, and such a retrograde step as endeavouring to shift the task on to owners of property will not be sanctioned by any legislative body. Moreover, the system is open to most serious objection from a sanitary point of view. Intercepting traps are provided for

the purpose of locking out sewer gas from the neighbourhood of houses, and so that in the case of a house drain being defective, the danger of admission of sewer air by this means is limited to that manufactured in the house drain itself. To advocate, therefore, that the owners of property must be put to the cost of providing intercepting traps to exclude sewer gas from houses, and at the same time to require them to bring it up to the house by another channel, the soundness of which can be guaranteed for only a limited time, is a species of folly which is engendered, it is to be feared, by over-zealous officialism which approaches subjects from one point of view only, and that of the Local Authority. The health of the community should, we need scarcely point out, have prior consideration; but in this case it has evidently, we think, been overlooked.

The efficiency or otherwise of high ventilating shafts was discussed at the meeting, and there appeared to be much confusion of opinion as to the value of these, Mr. Norrington, explaining the results of his experiments to test their power of extraction, from which it was shown that they were practically useless, while it was contended, on the other hand, with far from conclusive evidence, that such shafts were useful.

With regard to the contention of one or two surveyors, that intercepting traps on house drains should be abolished, we have no sympathy whatever. A drain without an intercepting trap is like a house without a door, and is open to admit evil associations of sewer gas, which, in the event of any part of the house drain being defective, would suffuse the dwelling with it. A very forcible illustration of it has been frequently shown where in the case of houses not provided with intercepting traps, and where indoor w.c.'s required repair, the plumber has removed the trap of this apparatus when the heated air of the dwelling has acted as an exhaust ventilator for the sewer, with most serious results to the occupiers.

The remedy for the ventilation of sewers will have, in our opinion, not to be looked for from surveyors. The question is one which belongs, as we have already pointed out, to the domain of the chemist and the Medical Officer of Health, and we venture to suggest that the only effective remedy lies in preventing by chemical means the decomposition of sewage, and at the same time by disinfection of the sewer air before it is allowed to pass out into the open air. This is the consummation to be arrived at, and the sooner that engineers and surveyors will concede it the sooner will it be reached, and their difficulties in connection with sewer ventilation be lessened.

Notes.

A Royal Commission.

An announcement of the utmost importance was made in the daily Press, towards the end of last week. The public was informed that the Government have decided to appoint without delay a Royal Commission to inquire into the bacterial treatment of sewage. This important decision has been arrived at on account of the pressure brought to bear by influential Sanitary Authorities. The remarkable success of the experiments at Exeter, Leeds, Sutton, and other towns, has also moved the Government to action. This action on the part of the Government is peculiarly satisfactory to us, seeing the important part we have been enabled to take in laying the result of investigations and labours of Mr. Dibdin and others before our readers. In our "Review of 1897" we ventured to predict that a "parting of the ways" had been reached in the treatment of this great and important question. But even the most ardent advocate of bacteriological treatment could scarcely have hoped for so early a recognition of the value of his researches. We shall await further announcements with interest.

Mechanical Filtration.

The article on "Mechanical Filtration," from the pen of Mr. Bristowe, which appears in our columns this week, together with the examples of what the process of which he is the able exponent has done, and which we present in the form of a supplement, should lead many of our readers to take a more active interest in a system of purifying sewage, polluted streams, trade effluents, &c., which, as Mr. Bristowe states, "is still most wrongly judged by many scientific experts." The E. H. Riddell system is one that combines efficiency and economy in a very remarkable way, and wherever it has been adopted most gratifying results have ensued. Many of the largest works in the Midlands have adopted the system, and it is from some of these that the samples of effluents—from dye works, paper mills, and woollen mills—we illustrate are taken. The sections represent the colours when the bottles are held to the light. We may add that we are indebted to Messrs. L. Hugh Bristowe and Co. for permission to utilise them, and also for an opportunity of personally investigating the system, which investigation, we are bound to say, has completely converted us to the cause of "Mechanical Filtration for Trade Effluents," as exploited by the E. H. Riddell system. In a future issue we shall illustrate and describe an installation of this process.

Sanitary Inspectors at Dinner.

Everybody concerned had cause for congratulation over the Annual Dinner of the Sanitary Inspectors' Association at the Holborn Restaurant on Saturday. There was a splendid attendance, the affair was exceptionally well organised, the *menu* and wines were good, and the speeches of a very high order of merit. Presentations were in the air and pleasant surprises were the order of the hour. Mr. Tidman, the energetic secretary, was, like Niobe, "all smiles." Our only regret was that we had to leave before it was all over, unwittingly foregoing our pleasant duty of responding for the Fourth Estate.

The Improvement of Westminster.

The Bill which it is intended to introduce in the present session of Parliament to empower a syndicate to acquire the thoroughfares of Millbank-street and Abingdon-street, to construct an embankment to the Thames, and to erect in place of the existing

old houses in that locality blocks of handsome, substantial modern buildings, is exciting considerable interest and opposition in the metropolis. The Westminster Vestry and the Chapter of Westminster are alike opposed to the Bill, and a good deal of opposition may be expected from other quarters. At a recent meeting of the inhabitants the fear was expressed that the Bill would be the means of driving a number of poor people from their homes, that many picturesque and interesting old houses would be destroyed, and above all, that the scheme would cost a very large sum of money. The case for the opponents to the scheme has been very vigorously argued by a writer in the *Pall Mall Gazette*, who fittingly puts his position as this—that the proposal is one to enable a company of speculators to make money, by converting a quarter where at present poor people live into a quarter where it is hoped that rich people will come to live.

Sanitary Aspects of the Scheme.

No one will deny that, as things are, the approach to the House of Lords from the south is not in keeping with the stately character of Westminster. Many of the old houses in Millbank-street are already falling into decay, and their demolition is simply a question of time. It is said that if things are allowed to go on as at present, these picturesque old houses will in the course of time come to be replaced by houses which, while retaining most of the disadvantages, will lose all the old charm of their predecessors. Then it is stated that the area is insanitary, and the preamble to the Bill sets forth that the scheme is conceived in the interests of the public health. Any scheme that is so conceived has, of course, our hearty approbation, but in the present instance one is inclined to regard this plea with a certain measure of caution. When a syndicate of private capitalists enter upon a scheme of "improvement" it is but natural to suppose that their dominating motive is not so much anxiety for the public health as the desire to promote a successful commercial venture, and to secure for those interested as handsome a return as possible.

Dangers of the Bill.

While, then, it will be readily admitted that there is great need for improvement of the vicinity of the Houses of Parliament, care must be taken to see that that improvement is carried out on the right lines. The proposal, if properly conceived, should effect a great change for the better. Even without going so far as to allege that the present locality is actually insanitary, there can be no doubt that there is abundant room for an improved sanitation, and a scheme of wholesale reconstruction would present an admirable opportunity for introducing modern sanitary methods and ideas where under existing circumstances they are hardly to be looked for. But we are by no means sure that these improvements, as proposed to be effected by the company who are promoting the Bill, would be such as to be most in the public interest. The writer in the *Pall Mall Gazette* expects that they will erect magnificent blocks of high-rented flats or monster hotels on sites which are of national importance; and though he probably goes too far in saying that such erections would be a disfigurement to Westminster, the citizens have a right to expect something better on such a site than buildings that would obviously be designed in the spirit of a profitable commercial enterprise.

An Alternative Proposal.

A very attractive modification of the proposed scheme is sketched by Mr. H. W. Brewer in last week's *Graphic*. He suggests that the street of 90ft. wide, which is to start from near the Victoria Tower and enter Horseferry-road 70 yards west of Lambeth Bridge, should be made to curve slightly to the east, so as to join Horseferry-road at the foot of the bridge itself. In the space between it and the proposed embankment there would be a long, narrow strip, which, instead of being covered with huge buildings which would shut out the view of the river and the Houses of Parliament, might be laid out as ornamental garden ground, forming a continuation of Victoria Tower Garden, from which it would be separated by a short road leading to the Embankment. Some such scheme as this was suggested by Sir Charles Barry in 1857, though on a larger scale. Mr. Brewer illustrates his idea by a sketch which certainly looks a wonderful improvement on the present aspect of the thoroughfare. It possesses the merit of opening up a noble view of the towers of Westminster, with a foreground of gardens, and would provide for a really worthy approach to the seat of Imperial Government.

Safeguarding of Water Supplies.

At the quarterly meeting of the Birmingham and Midland branch of the Incorporated Society of Medical Officers of Health, a very valuable paper was read by Dr. Bostock Hill on "The Safeguarding and Examination of Public Water Supplies." An interesting discussion ensued, as the result of which the following resolution was adopted:—"That in view of serious dangers to public health which may arise from the pollution of public water supplies, statutory power should be given to Sanitary Authorities to periodically inspect and take samples from the waterworks from which their districts are supplied." Of course, the warning afforded by the epidemic at Maidstone was referred to in the discussion as the "shocking example." The good people of that now notorious town will derive what consolation they can from the thought that their misfortunes have at least served this good purpose of awakening the people of the country at large, and Sanitary Authorities in particular, to a sense of the grave responsibilities that attach to the jealous preservation of our water supplies from the slightest possibility of the taint of pollution.

Food Products Adulteraton Bill.

The Council of the Society of Public Analysts, in their report on the Food and Drugs Bill of last year, give expression to their dissatisfaction that the draft Bill introduced by the President and Secretary of the Local Government Board did not embody the most important recommendations of the Food Products Adulteration Committee, the bulk of which should have been embodied in the Bill. The most impor-

tant of these recommendations—that referring to the foundation of a Court of Reference—the Council lay particular stress on. The Court of Reference, they think, should be constituted substantially on the lines laid down in the report of the Select Committee, with this modification, that it should include in its number one or more public analysts. Unless these points are attended to, the measure will not, in the opinion of the Council, do much to remove the difficulties that are at present experienced in carrying out the existing Acts.

The Paris Exhibition, 1900.

The Government have agreed to ask Parliament for a grant of £75,000 to provide for the expenses connected with the British section of the Paris Exhibition of 1900. The amount of the grant can hardly be said to err on the side of liberality; compare with it, for instance, the example of the German Government, which has sanctioned a grant in aid of 5,000,000 marks, or about £250,000. The Prince of Wales is the President of the Royal Commission for the Exhibition, and at the first meeting of the Commission, held at Marlborough House last week, his Royal Highness expressed the hope that the Treasury would be prevailed upon to considerably augment the grant, as the sum promised would hardly prove sufficient or adequate. The Exhibition, he said, was to be carried out on a scale of magnificence never before approached even in Paris, and the important influence it was expected to have on the industry and art of this country was indicated by the comprehensive character of the British Commission. A distinctive feature of the forthcoming Exhibition will be that the exhibits will be classified according to their character, instead of being grouped according to the countries which they represent, so that the products of any one kind, no matter from what part of the world they come, may be seen and compared together. It is to be hoped that due prominence will be given to the sanitary appliances of the day. They should form a most interesting exhibit, and we trust that British exhibitors will be well represented.

Threatened Pollution of Loch Katrine.

A detachment of Lanarkshire Volunteers have selected as the field of their Easter Manœuvres the country around Loch Katrine, from which the water supply of Glasgow is derived. An alarmist, writing to the Press, has pointed out the danger, involved in this proposal, of pollution of this famous water. It is true, no doubt, that the place is visited by thousands of tourists every summer; but at Stronachlacher Hotel, the only place on the loch where they stop, the sewage is carefully pumped up to specially-prepared filter beds on the hill, and the steamers are not allowed to discharge their sewage into the loch. The Volunteers will be placed, it is supposed, under no such restrictions. They will not live in the hotel; and as they may be expected to spend a good deal of their time on the lake in boats, there is a danger that a considerable amount of liquid and solid filth may find its way into the Glasgow drinking water. We trust, however, that the Authorities in charge of the manœuvres will have their eyes open to this risk, and will take sufficient measures to prevent its being incurred.

Public Health in Parliament.

The Home Secretary stated in the House of Commons, on Thursday of last week, that thirty-seven cases of lead poisoning, occurring in factories and workshops amongst boys under eighteen years of age, had been reported in 1897, two of which were known to have ended fatally. He added that the whole subject of lead poisoning was receiving his earnest attention, although he was not yet prepared to make any statement as to the steps which would be taken as to the process. Mr. Long, President of the Board of Agriculture, on the same occasion gave statistics showing the decline in the reported cases of rabies in Britain, since the muzzling regulations were put in force. The number in 1896 was 438, and last year 151, and this year only five cases are known to have occurred—a result which the Board regard as very satisfactory.

The Plague in India.

The plague in Bombay continues to spread. The deaths from this cause last week numbered 1257, an increase of 144 on the returns of the previous week. Among the latest victims we regret to record the death of Miss Florence Eva Morgan, acting lady superintendent of the General Plague Hospital and Nursing Establishment, who caught the infection and died on the 14th inst. As an indication of the effect being produced upon the course of business by the alarming ravages of the scourge, we hear that one of the Exchange banks issued a notice a short time ago to their customers suggesting that they should curtail their business with Bombay as much as possible; and now they have issued another circular, stating that, in consequence of the rapid spread of the plague, business with the Bombay Presidency should, in their view, be restricted as far as possible in view of the difficulties that may be anticipated in obtaining the payment of bills. Everything is getting thoroughly demoralised, and as yet there hardly seems to be a ray of light or hope. In spite of all the discouragement, however, the Government are keeping their heads perfectly cool.

The Influenza.

From the Registrar-General's return we learn that the influenza still rages in the metropolis with fatal results. Its latest influential victim is Mr. Wootton Isaacson, M.P. for Stepney. The doctors report a large number of patients down with the "grip," and many distinguished people are among the sufferers, but it may be hoped that the malady in a fatal form has begun to wane. There were only 87 deaths in London last week as compared with 98 in the preceding week, and 102 in the week before that. The figures therefore mark a distinct decline. In each of the last eight weeks there have, on the average, been just 70 deaths from influenza in London alone, the greater proportion being among elderly people. The epidemic has been the most severe that has been known for three years.

At a recent meeting of the Carnarvonshire Sanitary Inspectors' Association it was unanimously decided to amalgamate with the North-Western and Midland Association.

NOTES ON
PRACTICAL SANITARY SCIENCE.

By WILLIAM H. MAXWELL.

Assistant Engineer and Surveyor, Leyton Urban District Council, Author of "Drainage Work and Sanitary Fittings," "Ventilation, Heating, and Lighting," &c., Certificates of the Association of Municipal and County Engineers, and Sanitary Institute.

No. 50.—REFUSE DESTRUCTORS.

(Continued from page 165.)

Warner's Destructor.

Warner's[130] patent "Perfectus" destructor (Fig. 15), with its recent improvements, is one of the latest furnaces for burning house refuse, of which some 500 cells are now in use. This destructor is in operation at Hornsey, Bournemouth, Newcastle-on-Tyne, Winchester, Govan, Hyde, Royton, Bath, Southampton, and several other towns. In general arrangement it is very similar to Fryer's, but differs from it in having a special charging arrangement, consisting of a hopper with a movable bottom. A charge is put into the hopper and a plate put over it to prevent the escape of smoke and fumes. A lever is then moved which releases the bottom door and allows the refuse to fall on to the drying hearth. Another important improvement is the provision of dampers to the flues of each furnace, which can be closed during the process of clinkering, and so keep up the heat of the furnace during the operation. Special dust-catching arrangements are also included in the design, and sometimes forced draught produced by a powerful fan is applied.

One of the latest installations of Warner's Destructor is that laid down at Bath. These works have recently been described at some length in *Engineering*[131]. The refuse is tipped into feeding hoppers, which consist of rectangular cast iron boxes. There is a flap door upon an axis at the lower part, the door being controlled by iron levers. When it is required to feed in refuse, the lever is thrown over, and the contents of the hopper fall immediately on the hearth beneath, and the door is at once closed again. It is desirable that when the operation of charging is to be performed the door should be open as short a time as possible, to prevent the admission of cold air into the furnace at the back end, a consequence which leads to the cooling of the gases evolved, and also to paper or light refuse being carried into the flues.

The *furnaces* or *cells* are each 5ft. wide and 11ft. deep. The part where the refuse first falls constitutes a drying hearth, whilst the lower part has *rocking grate bars*, as shown, and here combustion takes places. The furnace doors in front are of the sliding type, and are constructed of cast iron with hollow backs, to allow of the attachment of baffled plates. Holes are made to give a small amount of air, and to provide a cooling effect.

Over the grate and the drying hearth there is turned a reverberatory firebrick arch which has openings for the exit of gases at the sides, as shown in the figure. These openings are fitted with flap dampers, which are operated by horizontal spindles passing through the brickwork to the front of the furnaces, where they are fitted with levers. In this way each cell may be operated independently of others, a feature which enables each workman to manage his own furnaces independently of the others—and the fires can be thus kept in better condition; besides which it affords a safeguard against dust getting into the chimneys and flues. When the dampers are closed, cold air is prevented from passing under the reverberatory arch and into the flues. The heated gases or products of combustion are taken by flues to the boiler-house, where they are used for generating steam.

At Royton four of the Warner cells are in use and are aided by a "cremator" heated by oil. The consumption of refuse here is equal to about five tons per cell per twenty-four hours, but this type of furnace will destroy up to about eight tons, according to the nature of the material. The clinker produced is equal to about 25 per cent. of the refuse.

Fig. 16 shows a recent improvement in arrangement of Warner's furnace, with the view of increasing its steam-raising capabilities. It will be seen that a forced draught has been introduced, and a tubular boiler is shown placed close to the cells instead of at some distance away in the main flue, as at Bath, &c. Mr. Richards, the city surveyor of Sydney, N.S.W., has recently reported favourably upon the furnace for dealing with the refuse of that city. The following extract from the *Sydney Morning Herald*, October 7th, 1897, gives some of the details of the report, and will be of interest in this connection:—The first of a series of reports by the city surveyor of Sydney, on the treatment and destruction of refuse, &c., in Europe was presented at a special meeting of the City Council held in October, 1897. This report is devoted almost wholly to methods employed for destruction of refuse, garbage, &c. Mr. Richards reports to the City Council that on his visit to England he "soon became aware that all England, in fact municipal authorities from all parts of the universe, were seeking to learn what destructor was doing the best work in England." After communicating with and interviewing surveyors and engineers who were regarded as amongst the best authorities in England, with many years' experience in such work, Mr. Richards selected from their advice, coupled with other information, the cities in which the most modern destructors were in use, and in his travels he visited no fewer than forty-five cities and towns. He visited and inquired into works at Manchester, Bury, Oldham, Royton, Cambridge, Hornsey, Southampton, Bournemouth, Eastbourne, Cardiff, Glasgow, Edinburgh, Leeds, St. Luke's, Lambeth, Kensington, Westminster, Cheltenham, Islington, Deptford, Leyton, Salford, Hampstead, Newcastle-upon-Tyne, Nottingham, Sheffield, Rochdale, St. Pancras, Battersea, Birmingham, Liverpool, Govan, Great Yarmouth, Bradford, Bristol, Huddersfield, Hyde, Warrington, Paris, Berlin, Dresden, Leipzic, Winchester, Vienna, and Brussels.

After describing the works in operation at various towns and cities visited by him, Mr. Richards says:—

"The real value of a destructor is that, however clumsy and costly the plan of burning refuse may be, it is at any rate effectual as a means of getting rid rapidly and completely of a readily decomposable, and therefore dangerous matter.

[130] Patent No. 18,719 (1888).
[131] January 3rd, 1896.

With proper destructor power and efficient daily collection of refuse, it should always be possible to get rid of dangerous material within twenty-four hours, before it has time to ferment and develope its peculiar powers. In no other way can this be done with so much certainty or so quickly as by fire. There is also this further advantage, that by so dealing with about one-third of the refuse we render another third saleable, and the remainder harmless. And the cost of this advantage is one shilling per ton on one-third of the refuse—fourpence per ton on the whole. Surely not an extravagant price! The free use of destructors seems to me the most efficient and safest mode at present known of doing this work and doing it effectually, and the Council would be prudent in making themselves safe by adopting it, and the sooner the better. That properly managed they need be no nuisance has been abundantly proved. Wherever they have been put in action prejudice has died out by degrees, and the anticipated disagreeables have not proved realities. That they should be considered of enough importance to be mentioned in comparison with the health of the city is un accountable."

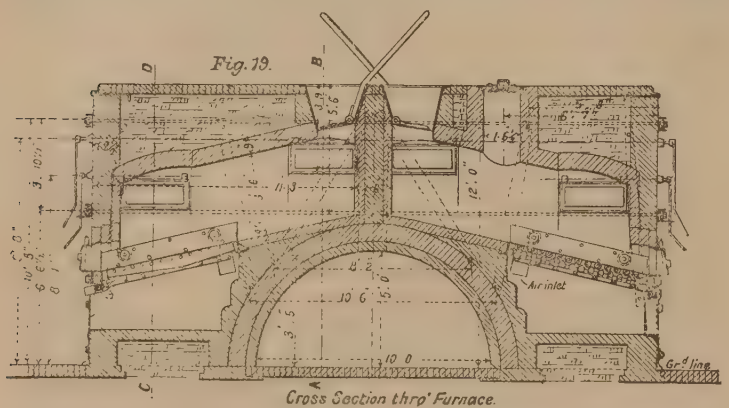

Fig. 15.—Section of Warner s Patent "Perfectus" Destructor.

While in England Mr. Richards called for tenders for the erection of a six-cell destructor in Sydney, the installation to consist of a six-cell destructor complete with all machinery and appliances, including clinker breaker and mortar mill. The shaft and primary arrangement to be of sufficient capacity for the further addition of six cells at any time after the erection of the first six that the Sydney Municipal Council may determine. The machinery to comprise one mortar mill, one clinker breaker, one engine, and feed pump for the boiler, large water tank, the shafting, belts and pulley for driving the various machines, and the steam pipes connecting the engine and pump with the boiler. The tender to include exhaust pipes and drain pipes from the steam cylinders. The contract to include the supply of all labour, tools, carriage, excavation, and cost of labour for working for six months, necessary to complete the whole of the works to the entire satisfaction of the city surveyor. All materials to be the best of their respective kinds and approved by the city surveyor or other authorised officer of the Sydney Municipal Council. Three tenders were received, namely, those from Beaman and Deas; Goddard, Massey, and Warner; and Manlove and Alliott (Fryer's). Beaman and Deas proposed a six-cell destructor with all fittings, boilers, shafting, in accordance with specifications submitted with all plant necessary for the electric lighting of the buildings at a cost of £9700.

Messrs. Goddard, Massey, and Warner's scheme includes six destructor cells complete, all brickwork for cells, buildings, flues, shaft, &c., two tubular boilers, valves, fittings on high-pressure steam engine for driving the mills and general machinery, one donkey-pump for feeding the boilers, vertical engine for driving the fans at such speed as may be necessary, one blowing fan, one tank (1000 gallons), an improved mortar mill for grinding clinker for mortar, one mill for breaking clinker suitable for footways and carriageways, shafting, pulleys, piping and

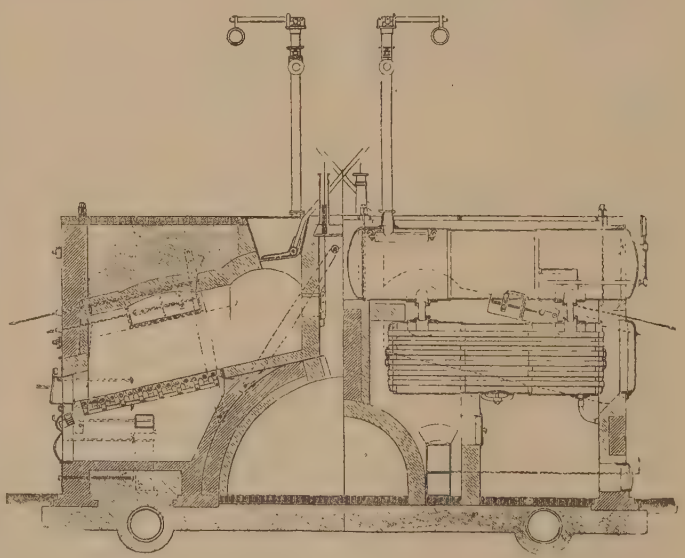

Fig. 16.—Warner's "Perfectus" Destructor with Boiler.

fixing same; chimney shaft, 150ft. high, with capacity for twelve cells; buildings consisting of brickwork and ironwork in the retaining walls, and roof work. Cost of works, £9580; electric lighting, £175; working for six months, £416.

Mr. Richards reports that Goddard, Massey, and Warner's scheme is the most suitable for the city of Sydney.

That firm undertakes to pay the same rates of wages for labourers and mechanics as are paid the day labour staff of the City Council, and engage local labour throughout. They are also prepared to allow the City Council to carry out any of the respective works in the event of the Council so determining, but they reserve to themselves the right of fixing and installing all the patented parts of the plant and appurtenances.

The conclusions arrived at by Mr. Richards are as follows:—That it is necessary in the interests of public comfort and health to at once establish means for the destruction of house refuse by fire. That the best and most suitable means for the treatment of Sydney's refuse is that by Warner's "Perfectus" patent refuse destructor. That for the whole quantity of house refuse collected twenty-four cells would be required. That street sweepings and gully soil may be turned to good account for top-dressing our reserves, parks, &c. That, with a view to the utmost economy, four refuse destructor depôts should be established—say, one Moore Park, South Sydney; one Ultimo, West Sydney; one near the vicinity of Kent-street North; and one at East Sydney, near Rushcutter Bay. That it would be advantageous for the Council to acquire and maintain stock and plant for cartage, not only of refuse, but for all purposes in city works; and that buildings for workshops, stabling, yarding of carts, &c., should be attached to each destructor. This is the custom in all important cities of England, and works very satisfactorily.

THE SANITATION OF DOMESTIC BUILDINGS.

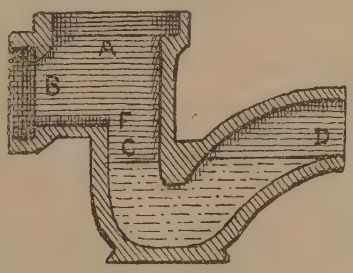
By Frank Latham, C.E., M. San. Inst., &c., Assistant Surveyor, Borough of Margate.

CHAPTER IV.

Section 2.

INTERCEPTION.

All communication between sewers and house drains should be cut off by means of a proper inter-



BUCHAN'S TRAP

Fig. 35.

cepting trap. In other words, in order to keep back from the houses any air out of the sewer, or air from one house drain, wherein there may be infection passing into the drains of another house, and thereby tending to spread the disease, an intercepting trap must be fixed, as otherwise all the house drains will be connected one with the other, and the sewers ventilated through the drains, by which means in time of an outbreak of infectious disease, contagion may perhaps spread through the defective drains and cause an epidemic. In cases where the interceptor is not used, it is tantamount to laying on the bad air from all filthy and neglected drains, including the line of sewers,

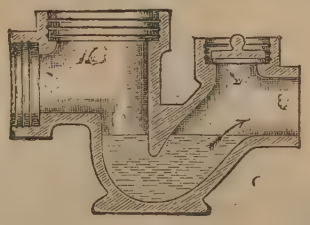


Fig. 36.

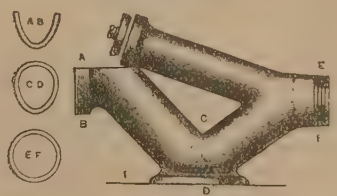
with the house drain, and all that is required is an outlet from imperfect work or an accidental fracture for the occupiers to have a plentiful supply of the mixture. The Model Bye-laws require such an intercepting trap to be provided between all sewers and house drains, with a pipe or shaft



"IMPROVED KENON"

Fig. 37.

carried up vertically on the house side of same, to act as an inlet air ventilator.

The intercepting trap should also without fail be used to disconnect the house drains from cesspools and similar receptacles, where there is no better method of drainage provided.

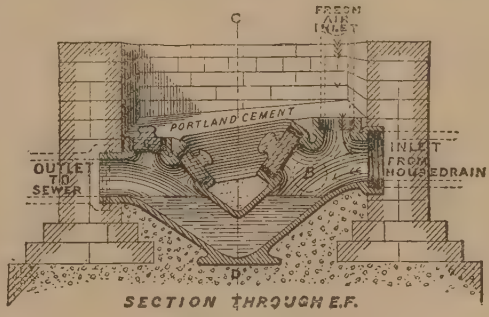


Fig. 38.

All intercepting traps should be of best glazed stoneware or iron, and at least one-twelfth the diameter of the trap in thickness, and free from any roughness or air-holes in the manufacture. They must be well shaped and with a water seal of 2½in. at the least. The interceptor should be set perfectly level, so as not to cause any undue impediment in the flow of sewage. Too large a trap should not be used, but a 4in. trap is sufficient for either a 4in. or 6in. drain and a 6in. trap for a 9in. drain.

Some of the principal intercepting traps used

are:—The "Buchan" trap, made by Messrs. J. and M. Craig, Ltd., as illustrated in Figs. 35 and 36, is one of the best forms of trap where no inspection chamber is used, as it can as a rule be kept clean and, if required, unstopped from the air inlet shaft, which should be at least 6in. in diameter. The

Fig. 39.

Improved Kenon" disconnecting trap, manufactured by Messrs. Crapper and Co., Fig. 37, is well designed to be used in an inspection chamber, as it affords a good raking arm into the sewer, and the mouth after leaving the open channel of the house drain, being egg-shaped, provides a deeper flow and better flush of sewage than others.

Sykes' patent interceptor is another ingenious production in connection with an inspection chamber, and when used no open channel is required, as the trap forms everything necessary, as will be seen by the following illustration (Fig. 38).

Winser's parallel intercepting sewer trap (Fig.

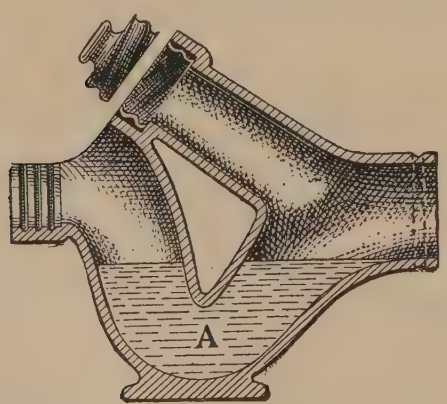

Fig. 40.

39), which has the inlet and outlet on the same level, is useful in cases where the fall between house and sewer is limited, and in all such cases an inspection chamber should be provided.

Fig. 40 shows a good interceptor, manufactured by the Albion Clay Company, Limited, a special feature being, that the raking arm is fitted with Sykes' Patent Screw Plug, which safely prevents the escape of sewer air into the chamber.

FROM WHENCE CAME THE FEVER TO LYNN?

DR. ST. GEORGE MIVART INVESTIGATES AND REPORTS.

LAST week we showed that, after careful inquiry, Dr. Mivart came to the conclusion that the blame for the advent of the epidemic could not be fixed either upon faulty sewerage and drainage, general sanitary conditions, or tainted milk supply. Having exhausted these possible sources of infection, he next proceeds to examine the arrangements for supplying the town with water. With the exception of some forty houses, or works, the whole of Lynn receives its water from the Corporation waterworks. This certainly simplifies matters in fixing the responsibility for any fault in the supply. There is no private company to denounce as working only for its own profit, with an utter disregard to the purity or otherwise of the supply. The Town Council alone is the responsible body.

As far back as 1892 Mr. W. Whitaker made a special report to the Waterworks Committee as to the source of the Gaywood river, from which the town's water is taken. Briefly, he states the supply is derived from springs that flow out of the base of the chalk, the water in which formation is held up by the underlying impermeable gault. "These streams are the result of the rainfall over the broad chalk tract rising to the east. Much of the water falling on the chalk sinks into it, and of this a part finds its way downward, until at some depth the chalk is saturated and can hold no more. The level of saturation varies roughly with that of the ground, being higher at the hills on the east than at the slope towards the outcrop of the underlying gault; the reason of the difference of level being the frictional resistance to the flow of the water through the chalk. The underground water-slope in the chalk of the immediate neighbourhood being westward, the springs are therefore merely the natural outflow of the water-charged chalk, the water finding its way out at the lowest available places, the slowness of percolation through the rock making the springs constant, though of course varying in amount, instead of their being very great at one time (after heavy rain) and dry at another, as would be the case if the water flowed through quickly."

All this is satisfactory, and the water thus obtained is by no means bad in quality. But some of the springs break out amidst "foul surroundings." For instance, one set at the north rise "directly from beneath the churchyard." This is bad enough; yet in another part, we are told, the most important set of springs "rise upon and around the slope whereon stands the farmstead known as Well Hall." In itself this is a very innocent statement, but when read in the light of Mr. Whitaker's report of five years ago, its innocency entirely disappears. He then said:—"The set of springs at Well Hall seems to be looked on as the fit receptacle for all the filth of the farmyard. One building is directly over a spring, the water of which may be seen oozing out from under the outer wall. At the time of my late visit, a liberal allowance of muck, of which I did not care to make a minute examination, had been thrown down about as near as possible to others of the

many springs there." Let it be remembered this report was given to the Town Council, through its Water Committee, in 1892.

But it does not stand alone. Dr. Bruce Low, the Medical Officer of Health, also solemnly warned his Authority of the terrible conditions under which it was deriving the town's water. In a special report then made he plainly stated that "The feeders of the river receive more or less directly the slop water of Grimstone village, while soakage from privy pits and refuse heaps, as also drainage from farmyards and horse-ponds sooner or later find their way into these tributaries. Two of the springs rise directly from beneath Grimstone churchyard. In addition to the above sources of impurity, the slop waters from the hamlets of Roydon, Bawsey, and Pot Row similarly find their way ultimately into the stream. At Grimstone, and again at Roydon, I saw the overflow pipe of a cesspool, receiving contents of water-closets, discharging into a water-course which flows into the Gaywood River. Similarly, the drains from a slaughter-house, a public-house urinal, and the washings of a laundry empty into water-courses which discharge directly into the stream."

In the face of such warnings as these, it would naturally be thought that some stringent measures would be adopted to effect an alteration. At any rate, this was the idea entertained by Dr. Mivart, and great was his surprise and disgust on paying a visit to the same spot to find exactly the same foul surroundings as those existing in 1892. "The same," but with some additions, "as if these sources of pollution were insufficient." He says, "I found on the date of my visit an immense heap of refuse and farm manure close to the edge of the stream. The inhabitants of two cottages, situated just below this point, obtain water by 'dipping' from the stream, and the enormous quantity of mussel shells thrown upon the very edge of the stream immediately adjacent to this 'dipping' place is significant of the indifference of the population of the district to the purity of their water supply." Whatever possessed the Town Council (especially with the knowledge of past epidemics and disasters) to allow such foulness in a place within its jurisdiction passes our comprehension.

But the story of pollution is not yet complete. Dr. Mivart continued his investigations, and in the following paragraphs he claims to illustrate the dangers to which river water is exposed:—

"Among the sources of serious contamination of the river is a brook falling into it, about two miles from the intake of the public water supply. This brook receives from a ditch the drainage from the farmstead of Waveland. The privy arrangements at the farm are very defective, and the overflow from the privy pit appears to mingle with the drainage from the farmyard and slop-drain. The farmhouse is in the occupation of two families. I was informed that in one of them there had been repeated attacks of diarrhœa during the past summer. Great complaint was made here of stench from the house drain; and, as a matter of fact, at the time of my visit this house drain was being cleared out, whereby the flow of foul liquids into the brook, and thus to the Gaywood River, was being rendered more direct.

"Coming now to Gaywood Village, a mile or so above the intake of the town water supply, the river flows by gardens which abut upon the river. Here in the course of my inspection I discovered several privies placed actually upon the brink of the stream. It is true that in several instances these privy structures were provided with pails said to be emptied upon the gardens from time to time; but there can be no doubt that even their presence in such situation conduces to risk of fæcal matters being washed out into the stream at seasons of heavy rain.

"Adjacent to the village of Gaywood are certain ditches which are only prevented from communicating directly with the river by a thin barrier of clay puddle. These ditches receive drainage from refuse heaps, back yards, a small farmyard, and also the liquid soakage from privies, and in one case the drainage from a patch of kitchen garden upon which previous to the heavy rainfall of September 29th the contents of a large cesspool had been emptied. Though these ditches are in ordinary circumstances prevented by the thin barrier of puddle from communicating with the river, there cannot be the slightest doubt that on the occasion of heavy rainfall they become bank full, and overflowing their dry puddle barriers pour their accumulated foulness into the river.

"At the intake of the waterworks the river water flows through earthenware pipes directly to the settling pond or reservoir known as the Long Pond. Between the river and the pond these pipes are at a varying depth beneath allotment gardens, which are largely the property of the Corporation. Having ascertained that these conduit pipes had not been examined for an unknown period of time, variously estimated at from 10 to 20 years, I had the ground opened over them close to the intake. The pipes were reached at a depth of a little over 3ft., and were found to be leaking so freely at the joints that a pump had to be employed in order to get rid of the escaping water and enable the work to be continued. The pipes are not bedded in concrete but lie in clay, covered by thick heavily manured garden mould. A few feet from this spot the tenant of a garden was in the habit, as he informed me, of emptying every week the contents of a privy pail.

"In the Long Pond the water has ample facilities for further pollution from the washing into it of surface refuse and the soakage to it of liquid from the heavily manured allotment gardens which come down almost to its brink. From a refuse heap close to the pond I observed the clearly marked course of a stream which in time of rainfall had flowed into the pond. As there is a public 'right of way' along one side of this pond which gives access to the allotment gardens, it is impossible to exclude children from the locality. And I was informed that in consequence of the habit they had of paddling with their feet in the water a watchman had at certain times to be posted at this spot."

The result of the examination here recorded confirmed the opinion expressed by the local Medical Officer, that the water had "multifarious opportunities for becoming polluted by human excrement, not to speak of other impurities directly discharged into it, or washed into it, or washed into the stream by heavy rains or melting snow.".

He further points out that notwithstanding chemical examinations of the water by the most eminent analysts, one of whom reported on it as "subject to contamination with animal refuse, nd

another, after analysing eight separate samples, condemned each as "unfit for drinking purposes" —still no action was taken. Yet another warning was given. The medical men of the town wrote to the public Press on the danger existing in their midst. In this letter they stated :—

"Brought as we are into daily contact with sickness and suffering, we keenly feel how lamentable is the amount of preventable disease which exists amongst the inhabitants of the town. Probably no single cause operates more potently in producing this than our impure water supply. Whilst freely admitting that the improvement of our water supply may entail an addition to the rates, we cannot think, even from a pecuniary point of view, this is for one moment to be compared to the advantages we should derive from an abundant supply of pure and wholesome water. To take only one water-spread disease, namely typhoid fever, it is a noteworthy fact that the last epidemic, which unfortunately still lingers amongst us, cost our Board of Guardians £149 16s. 8d., and has left us widows and orphans whose permanent support amounts to £43 15s. 4d. annually. The victims were, however, by no means confined to the recipients of parochial relief. Altogether 131 cases occurred, of whom 21 lost their lives, besides which there were notified 107 cases of continued diarrhœa, considered to have been abortive typhoid. Each case of typhoid fever incapacitates the patient from work for a period varying from six weeks to three months. Such a prolonged illness entails heavy expenses for nursing, extra nourishment, medical attendance and the like, as many families know only too well. We have none of us the slightest doubt that the above epidemic arose from our polluted water supply, and from it alone."

Nevertheless, incredible as it may appear, a large and influential section of the inhabitants of Lynn maintain, or at any rate have maintained until now, that this water, manifestly polluted though it be, is of excellent quality. One individual went so far as to exhibit in his window during the height of the epidemic a vessel of water drawn from the town mains, with a placard attached stating that no better water can be obtained.

Reviewing these facts, Dr. Mivart expresses his opinion that the heavy rainfall of August 9th may have been the cause of the increase of fever noticed early in September, the cases though widely scattered over the town in a fashion consistent with water causation of the disease, being too few in absolute amount at that time to definitely convict the water service of having brought it about.

Not so, however, as regards the exceptional rainfall of the 29th of September. This was followed, says Dr. Mivart, "at an interval of three weeks, by an outburst of the fever on a very large scale indeed. On the 20th and 21st of October the notified cases of enteric fever in Lynn and Gaywood suddenly amounted to twelve. Next day they were twenty-six, and in the four succeeding days to the 26th of October no less than seventy-five additional attacks were notified. And the fever cases of this outburst, be it noted, were distributed from end to end of Lynn and Gaywood, in circumstances which, as I have already stated, left no escape from a conclusion that the outburst had been caused by the water supply. There can be no doubt at all, then, that the epidemic, as such, was due to infection of enteric fever gaining access to the waterworks as a result of the rainstorm of the 29th of September. Why wholesale befoulment of the Lynn public water service effected on one occasion comparatively little mischief, and on the next proved altogether disastrous in the above fashion, is a question which cannot at the present stage of our knowledge be definitely answered. Possibly the storm of 29th September, in that it was as a heavy downpour more widespread than that of the 9th of August, may have (by the floods which it caused) tapped, so to speak, sources of dangerous pollution of the Gaywood river which were not reached and therefore not flushed out into the stream by the even heavier but more localised August rainfall. This, however, is mere surmise. Moreover, we are by way of learning that outside the animal body the microbe of enteric fever is subject to conditions which, within a short space of time, may check altogether its multiplication and annul its virulence, or may greatly enhance its activities in one or both these directions."

The measures taken to stamp out the fever are described by the Inspector, and he concludes by stating that the best was perhaps done in the circumstances to mitigate disaster that should never have occurred. For it cannot be too strongly insisted on that, so long as the supply of drinking water for the borough is derived from the Gaywood River, so long will the borough be at the mercy of water-borne disease. Ever since 1876 the more thoughtful section of the inhabitants have been engaged in a struggle, the bitterness of which only those resident on the spot can realise, to obtain for themselves and their families a wholesome supply of drinking water. In 1875, Mr. Hawksley, being consulted by the Town Council, recommended that the water should be brought in pipes from one of the springs, direct to the town. Since then, until recently, in vain have Medical Officers of Health, and engineers, and surveyors protested, and experts like Mr. Whitaker, F.R.S., and Mr. Mansergh, C.E., reported and advised. The party with whom no argument but the one as to the cost had any weight were too strong. It might certainly be thought that after the severe outbreak in 1892, which was traced in the clearest manner by Dr. Bruce Low to the infection of the public water supply, all opposition to a new source of supply would cease. But such was not the case. In the end, however, a Provisional Order of the Local Government Board enabled the Town Council to carry out a scheme which might otherwise have been frustrated by the opposing section of the inhabitants. The works in connection with the new scheme for bringing water from deep wells in the chalk near Grimstone are being actively pushed forward, but Dr. Mivart was informed that it would be six or eight months before they were completed.

This is the story of how the fever came to Lynn. We commend it to the consideration of those false economists who oppose every public improvement because of the expense. By refusing to accept the advice of its own officers, the inhabitants of Lynn may perhaps have saved a few pence in the pound on their rates, but they have inflicted great suffering on many families and shortened many lives by their misguided parsimony.

SEWAGE PURIFICATION.

MR. H. GILBERT WHYATT, A.M.I.C.E., Deputy Borough Surveyor for Salford, read a paper entitled "The present position of the sewage purification problem," at a meeting of the Sanitary Inspectors' Association (Lancashire and Cheshire Branch) held at the Royal Technical Institute, Salford, on Saturday afternoon, the 12th inst. Mr. J. T. Shawcross presided, and there was a large attendance.

At the outset of his paper Mr. Whyatt remarked that it would be possible to describe in two words the present position of the problem; he proposed, however, to take a comprehensive view of the situation. The first inquiry by the Local Government Board was undertaken over forty years ago, a second was commenced in 1865, and a third in 1868. The third inquiry was the most important, as it was directed to the rivers of typical manufacturing districts in England and Scotland. In their third report the Commissioners said they considered that the right way to dispose of town sewage was to apply it continuously to the land, as it was only by such application that the pollution of rivers could be avoided. Referring in detail to the first report of the 1868 Commission, which dealt specially with the Mersey and Ribble basins, Mr. Whyatt spoke of the importance then attached to the manurial value of sewage sludge. Eventually this idea of manurial value was dropped, and experimenters would have been content with a chemical treatment which would meet the remaining difficulties, but their efforts were futile, and now only "patentees" had any hope of success. The "international" and "electrical" systems were brought forward, and the former had been successfully adopted in many places. The "electrical" was very successful also, but its expense was great. Mr. Whyatt dealt at considerable length with the process of treating sewage by biological agency, which, he said, dated no further back than 1882 or 1884, and about which the report of Mr. W. J. Dibdin (late chemist to the London County Council) and Drs. Sorby and Dupré clearly established the position that the foul matters in sewage were ultimately destroyed by the action of living organisms—the process being biological and not chemical—and it was when these organisms were not allowed full scope to exercise their beneficent life action that putrefaction resulted. Scott Moncrieff, Lowcock, and others had conducted experiments on these lines. In Salford experiments had been going on for about ten years, and much time had been spent on various patented processes, chiefly chemical. About five years ago the Committee turned their attention to artificial filters. The first set of six filters were arranged at three heights, with a ventilation floor between each 2oin. of filtering material. Two filters were composed of gravel and sand, two of coke breeze, and two of cinders, and very good results were at once obtained from them all. Cinders proved the best filtering medium. The experiment was continued for fifteen months at an average rate of 500 gallons per square yard per day, with very successful results. It was then wished to prove the advantage of a preliminary "roughing" filter and varying degrees of aëration; and this experiment was still going on. The filters were tried at varying rates of flow, and so long as a filter did not choke up the effluent was uniformly good. If the filter choked up it was found that by leaving it idle for a week or two it would recover itself and again take the sewage perfectly. In 1895 two filters 8ft. deep were made in order to ascertain whether a deeper mass of filtering material would deal with a larger quantity of effluent, and it was found that while a 5ft. filter would deal with 500 gallons per yard daily, an 8ft. one would deal with 800 gallons. In 1896 the filters were run practically continuously for twelve months at the rate of 1000 gallons per square yard per day, then for a short time at 500 gallons, and now at 700 gallons, the only rest being for a short time daily whilst the small pump supplying them was cleaned. Contrary to expectations, they stood that severe test. In place of the sprinkling troughs spray jets were now used. The surface of the filter was perfectly open and water was not allowed to collect anywhere. There had been no appreciable growth of the brown sewage fungus since 1895, and the bacterial filters had been protected by a "roughing" filter of fine gravel. Some twenty-five precipitation experiments had been tried, and the effluent of all passed through the bacterial filters with good results. The Corporation had resolved to spend £80,000 in altering the works and laying down bacterial filters, but the Local Government Board had refused its sanction unless the Corporation included a sum to cover the purchase of land over which the filter effluent might be turned and further purified. Mr. Whyatt considered the time had come when the Local Government Board should be roused from its state of "agnostical immobility" and take upon itself to examine whether there was not the efficiency in bacterial filters that was claimed for them. Mr. Whyatt was accorded a vote of thanks at the conclusion of the proceedings.

WATER ANALYSIS.

A CASE which showed a remarkable divergence of opinion among experts as to the purity of water came before the Maidstone Police Court, and excited great public interest, following so closely on the Local Government Board inquiry into the cause of the typhoid outbreak in the town. A lady named Prosser was summoned by the Urban District Council for neglecting to close a well, the water of which was declared by Dr. Adams, the Medical Officer and County Analyst, to be polluted and quite unfit for dietetic purposes without previous boiling. On the other hand, Dr. Gregory, a Fellow of the Institute of Chemists, who had also analysed a sample of the water, certified it to be of great organic purity, and perfectly safe for drinking and domestic purposes.

Professor Wanklyn, the inventor of the ammonia process in analysis, which is used by almost every analyst in the country, including Dr. Adams, corroborated Dr. Gregory, and stated that on Dr. Adams's own figures he had come to the conclusion that the water was pure and unpolluted, and quite safe to drink. The analysis in this case disclosed the presence of very little albuminoid ammonia, and that fact alone proved to him that the water was a good one.

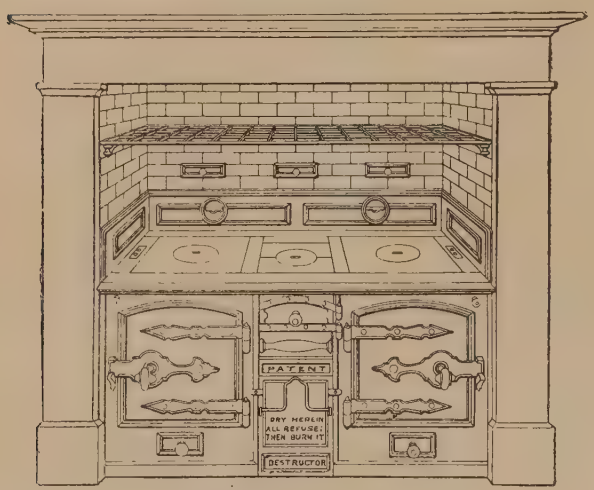
In the end the Bench adjourned the case in order that a sample of the water might be analysed by the authorities at Somerset House.

A DOMESTIC REFUSE DESTRUCTOR.

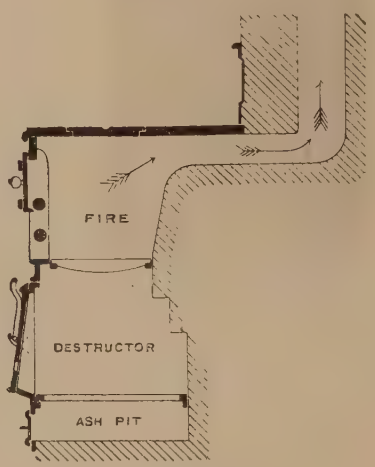
At a time when refuse disposal is "in the air," it is hardly surprising to find an adoption of the methods which obtain in communities to the needs of the individual householder. The practicability of such an innovation becomes obvious when the possibilities are minutely examined, and it has been the happy notion of Mr. J. B. Petter, of Yeovil (inventor of the well-known "Nautilus" grate), to carry out the idea to its practical issue. Recognising that what can be done on a large scale on behalf of the community at large by the local Sanitary Authority might be equally well done at first hand by the individual, he has designed a domestic refuse destructor which, combined with the ordinary kitchen range, performs the function of destruction on the spot, thus relieving the Sanitary Authority of one of its most onerous duties.

The destructor is a simple apparatus, which, combined with a kitchen range, provides a means of destroying, day by day, all house waste and refuse, such as potato peelings, cabbage leaves, fish bones, &c. &c., thus doing away with the annoyance caused by the accumulation of such unsavoury rubbish in the dust-bin. The ashpit of an ordinary range is enclosed, making a chamber into which the refuse is placed, to be dried by the heat of the fire; all greasy or fatty matter is effectually absorbed by the ash falling through the fire-bars, and when everything is reduced to a combustible condition it is shovelled into the fire. A constant in-draught is ensured by means of holes in the door of the destructor, whereby the fumes are carried up through the fire, and thence into the chimney. This, with the close and accurate fitting of the door, prevents the escape of any vapour or smell into the kitchen. Thus use is made of the ordinary kitchen fire in the actual work of destroying the refuse, and the slow combustion character given to it by the closing of the ashpit, while rendering it hotter and more effective, at the same time lessens the consumption of fuel.

A striking testimony of the value of Mr. Petter's patent has been afforded by Dr. Garland, Medical Officer of Health, Yeovil, who, having adapted the destructor to his own kitchen range, is, it must be admitted, fully qualified to give an opinion concerning it. Dr. Garland considers the invention, from a sanitary point of view, the greatest boon ever conferred on householders, not only on account of its effective work as a destroyer of noxious exhalations arising from culinary waste, but also on account of the economy which is evident in the consumption of fuel, which he has proved by experience to be considerable. Dr. Garland, in short, endorses its claim to practical utility in every respect, and predicts that there is a great future in store for it. While the general adoption of such an invention can hardly hope to relieve Local Authorities of their responsibilities altogether, or to render the use of refuse destructors by such Local Authorities unnecessary, there is not the slightest doubt but what its general adoption would minimise their work considerably, and it is perhaps not too much to look forward to a time when "every man his own dust destructor" will be a *sine quâ non* of household sanitation.



A Modern Kitchen Range fitted with Patent Domestic Refuse Destructor.



Section through Fire.

London, W.C.—The Board of Works for the Holborn district is about to appoint an additional Sanitary Inspector at a salary of £120.

The Relative Cost of Works of Sewage Disposal. — A letter on this important subject by Mr. C. Chambers Smith, C.E., Sutton, Surrey, in reply to the letter by Messrs. Cameron, Commin, and Martin, which appeared in our issue of last week, is unavoidably held over.

TO OUR READERS.

The Editor solicits the co-operation of readers in making The Sanitary Record *more attractive by means of pen-and-ink sketches, photographs, and diagrams. There are many phases of sanitary work which lend themselves admirably to illustration. By this means not only individual articles, but the journal as a whole will be heightened.*

MECHANICAL FILTRATION.

By FREDERICK BRISTOWE.

IT may perhaps astonish some people to learn that mechanical filtration is still grievously misunderstood, even by those who are supposed to be best qualified to express an opinion on such a subject. For some years past mechanical filtration has received a great deal of attention in certain quarters, and the results that can be achieved to-day are so convincing that any one who will consent to investigate the matter with a previously unbiassed opinion, cannot fail to be convinced of its utility, economy, and efficiency.

There are, of course, some people with whom it is useless to argue, as they have made up their minds that mechanical filtration is an impossibility. Such people, even if you succeed in showing them a plant of mechanical filters actually in operation—a plant which, for the sake of argument, may be treating a dye-works effluent, and producing therefrom a clear, bright effluent—will ask you where the towns main comes in, or some such equally ridiculous question.

MR. FREDERICK BRISTOWE.

In quoting this instance it must, of course, be understood that a mechanical filter to be of any practical use must be in all respects self-contained, and constructed on scientific principles. For instance, a manufacturer when going into the question of filtration, will tell you that he requires a certain quantity of water per day. This water must attain to a certain standard of purity, which standard must be maintained continuously. He will also tell you, in all probability, that he has very little room to spare, and therefore cannot provide any large amount of storage. A mechanical filter to suit these requirements must therefore be arranged in such a manner as to supply the required quantity of water continuously, and at the same time be capable of maintaining the standard of purity.

Up to this point filtration is, comparatively speaking, an easy matter. The water being filtered naturally leaves a large amount of sediment in the filter, which, without mechanical means, it is either impossible or too costly to get rid of without losing the filtering material.

In a properly constructed mechanical filter the process of washing and cleansing the filtering medium is a very simple operation, as the filter can be cleared in the course of a few minutes, without losing any part of the filtering medium, or stopping the supply of clean water to the works. A mechanical filter can be so arranged as to work under any pressure required, and by this means will save any labour or expense in extra pumping, as the water can be forced through filters placed on the main supplying the works in question.

In respect to the question of economy there is a great deal to be said in favour of mechanical filtration. To begin with, there is the enormous economy gained in space occupied, which in all works is of the greatest importance. Then, again, a properly constructed mechanical filter is to all intents and purposes automatic, thereby effecting a considerable saving in labour, as opposed to the open filter bed process. Another important point is the rapidity with which the process of filtration can be effected, thus obviating the nuisance of which so many complaints are heard in manufacturing districts of the fouling of their clean water reservoirs by the dirt in the atmosphere.

Mechanical filtration is still most wrongly judged by many scientific experts. Either they refuse entirely to investigate the question at all, or they imagine that mechanical filtration is setting itself up in opposition to all other processes of purification by filtration. This, idea is, of course, to anyone who knows anything of the subject an absolute misconception, not to say a deliberate false statement, for while it is evident that a very large percentage of purification can be effected by means of proper mechanical filtration, even the most enthusiastic promoter of mechanical filtration must admit that as regards certain impurities in solution, it is impossible to guarantee absolute purification by this process alone.

The great claims of mechanical filtration are

that it can work very quickly and efficiently, that it affords the cheapest, the simplest, and the readiest means of clarification, and that rather than being in opposition to many of the leading principles of the day, it would save much argument and trouble, to say nothing of expense, if it received more general attention, and its results were more universally admitted.

THE PLAGUE IN INDIA.

EARL SPENCER presided last week at a lecture on the plague in India, delivered at the Imperial Institute by Mr. H. M. Birdwood, C.S.I., M.A., LL.D. There was a large audience, among those present being Countess Spencer, the Earl of Northbrook, Sir Stewart Bayley, Sir Owen Tudor Burne, Sir Frederick Abel, Sir John Jardine, Sir Richard Thorne Thorne (Principal Medical Officer of the Local Government Board), Sir Juland Danvers, Sir George Birdwood, Sir M. Bhownaggree, M.P., Lady Honora Cadogan, Lady Wood, Lady Pearson, Sir William Roberts, Sir Charles Lawson, Sir Dyce Duckworth, and Surgeon-General Webb.

Among the letters of apology for absence read by the Secretary was one from Mr. John Holland, senior collector at Bombay, in which he paid a high tribute to the devotion shown by Mrs. Birdwood in visiting the plague-striken natives.

In introducing the lecturer, Lord SPENCER disclaimed any special knowledge of Indian affairs. He was afraid that in the past want of interest or want of information had been too often displayed by our people in Indian matters, but he was glad to see so large a meeting that day. We had the greatest sympathy with the people of India in their distress, and the highest admiration for the patriotic work done by all those who were trying to get rid of the plague.

Mr. BIRDWOOD commenced a historical comparison with the great plagues of the past, the sicknesses and black deaths which swept over Europe in the middle ages, which devastated London in 1665, and did not finally disappear until in the present century. As late as 1878 there was a recrudescence of the mediæval plague on the banks of the Volga; and perhaps we have not even now altogether banished it to the East whence it came. It is rather a curious fact in connection with the spreading of the plague that it never invaded Africa with success, or got beyond the Northern coasts—a fact which, perhaps, the bacteriologists of the future will be able to explain. Various causes have been assigned as the origin of the plague—that of the drowned corpses of the Chinese floods being the most popular—but the immediate cause of infection is a tiny bacillus.

The lecturer threw a photograph of a cultivation of the bacillus upon the screen. It is a tiny body of what is sometimes called the lead-pencil order of micro-cocci—cylindrical in shape and, perhaps, two and a-half times as long as it is broad. This little unicellular being is only the one ten-thousadth part of an inch long, by the one twenty-five thousandth part of an inch broad, and it is hardly to be wondered at that the bacteriologists know little about his protoplasmic constitution or the kind of treatment which is fatal to him as yet. They have, however, classed his unicellular body, which, from Mr. Birdwood's description of him, appeared to belong to the "mycetozoa," as a vegetable, and it seems pretty certain that he is not stimulated by cold water. Nearly all the great plagues of the past have been favoured by hot and dry years; the year of the Great Plague of London was unusually torrid; and 1896 was the hottest summer that Bombay or India had experienced for fifty-one years. The worst months were the February and the March of 1897, which were very hot and dry, with the usual dry north-east wind blowing over India. The plague began to abate as soon as the wet south-west monsoon swept round in the middle of April. The medical authorities, at any rate, were convinced that water was a terror to the microbe; and every house that was affected was treated as if it had been a burning building. The municipal fire engines were turned upon it, and it was deluged inside and out. Some authorities professed to regard this as an expensive and useless remedy; but another remedy suggested by Lord Lister, of sluicing all drains with lime water, was of undenied benefit. In one other respect the plague respected the old tradition concerning it. It was, as Piers Plowman witnessed, "a poor man's plague." The greatest sufferers were the Hindoo outcasts; next to them the Hindoos. The Mohammedans suffered little, the Parsees rather more; but the Europeans, whose lives were led amid the best and most sanitary conditions, suffered least of all. There are two other points to be noticed with regard to the plague. Inoculation proved an extremely serviceable remedy, and whereas in the Great Plague of London 68,000 people died out of a population of 490,000, in Bombay only 20,000 died out of 900,000.

One of the most interesting portions of the lecture was the reference to the part played by rats in spreading the disease. It is thought that in a newly-attacked district the imported germ is not strong enough to infest men, but seizes on the rats. The death of the rodents is not the first phenomenon, however. It is preceded by a migration, and in Thana the "Rats' Progress" has been traced from south to north, through towns and villages which were not infected until they brought the plague.

A vote of thanks to Earl Spencer and Mr. Birdwood concluded the proceedings.

HEALTHY TOWNS AND VILLAGES.

SOME POINTS FOR PUBLIC BODIES.

A LECTURE on the subject of "Healthy Towns and Villages," one of a series which Miss Alice Ravenhill, of the National Health Society, is delivering in Leeds, was recently given in the Lecture Hall of the Yorkshire Ladies' Council of Education in Albion-street. Miss Ravenhill, in the course of a thoroughly practical discourse, touched on the question of the Rivers Pollution Act, pointing out that while various effluents were prohibited from entering a stream, there were at the same time so many saving clauses that Authorities were often powerless. It was, however, possible for a number of towns to join together to get powers enabling them to deal with the question, and Leeds, Bradford, and other places had combined to form

the West Riding Rivers Board, which had done something to institute proceedings, and had not been discouraged, even by failure to obtain convictions. But, speaking generally, the provisions of the law on the subject were so complicated that people had let the Act alone. They wanted a large amendment of the law, which would give full power to Local Authorities. In Leeds they had a bye-law which made it necessary for the Medical Officer's certificate to be obtained before any trade effluent could be passed into the river, but that did not apply to neighbouring towns. The Act at present was cumbersome, unwieldy, and very little good to the community. In the matter of open spaces Leeds compared very favourably with Manchester. In the latter city the average of open spaces to population was half an acre per 1000; while Leeds in 1895 had two acres, and since then had added other recreation grounds. The Allotments Act had proved complicated and difficult, and provided for no security of tenure, while the land was let at double the rate at which it was held by a tenant-farmer. The municipalisation of tramways was always desirable, because the Corporation could assist in that way in taking the people to less congested parts. Leeds has adopted the Baths and Wash-houses Act, but as yet there had not been great haste in erecting baths. It was very desirable that some provision should be made for mothers being able to give their children a bath at least once a week, because in the poor districts there was not much accommodation for such a thing in the cottages. What the lecturer would suggest was what had been already adopted in some of the large towns in Yorkshire, namely, that mothers should be allowed to wash their children at a charge of a halfpenny each, a plan which would assist materially in the promotion of public health. Miss Ravenhill then alluded to the importance of vaccination and the desirability of some method of keeping the general body of the people fully cognisant of the evils which early in the century had resulted from the lack of inoculation, because the comparative immunity from the disease which existed now-a-days made them forget what a terrible malady small-pox was. The importance of the Notification of Infectious Diseases Act was also emphasised, the lecturer referring at the close to the new isolation hospital at Manston, where the accommodation was as yet inadequate, though the fever-rate of Leeds was high. The matter was one for the ratepayers themselves, who should see that there was no delay.

LONDON AND WORKMEN'S DWELLINGS.—At Tuesday's meeting of the London County Council (the last prior to the election) it was stated by Mr. Alfred Smith, chairman of the Housing Committee, that up to March 31st, 1897, the Council had in occupation dwellings erected and purchased at a cost, including all expenses of supervision, of £267,254 5s. 2d. Tdere were at that date in course of erection further buildings estimated to cost £60,209. Those, with one exception, had now been completed, and were occupied. The total expenditure on dwellings erected and in course of erection (including the cost of the land) had only been £387,458, for which sum the Council had provided accommodation for 6606 persons, and in addition had provided 17 shops, 100 workshops, 12 stables, and 20 sheds.

Inc. Society of Medical Officers of Health

METROPOLITAN BRANCH.

AN ordinary meeting of the members of the Metropolitan Branch of the Incorporated Society of Medical Officers of Health was held on Friday afternoon, the 18th inst., at 197, High Holborn, the offices of the St. Giles' District Board of Works. Dr. Edmund Gywnn, Hampstead, the president of the branch, occupied the chair, and those present included Drs. Louis C. Parkes, Sidney Davies, Reginald Dudfield, M.A., M.B.; J. F. J. Sykes, M.D., D.Sc.; J. C. Jackson, D.P.H.; F. J. Allan, M.D.; and O. Field, M.D., Wandsworth, the hon. secretary.

Dr. LOUIS C. PARKES, M.D., D.P.H., the Medical Officer of Health for Chelsea, opened a discussion on "Sewer Ventilation." He said that until the researches of Parry, Laws, and Andrews, it was generally held that sewer and drain air was liable to contain the poisons of enteric fever, cholera, and other diseases—a view which led to the free ventilation of sewers, on the ground that the more sewer gases were diluted with fresh air the less would be the danger. Hence the provision of surface gratings and the modern practice of trapping, disconnecting, and separate ventilation of house drains. From the researches of Haldane, Carnelly, Parry Laws, Andrews, and others, it was found that micro-organisms in sewer air appeared to be exclusively derived from the outside atmosphere, and not from the sewage. Microbes, which abound in sewage in inconceivable numbers, were not found in sewer air. If, then, sewer air did not contain infectious microbes as supposed, why perpetual disconnection and separate ventilation of house drains? Why have traps and gullies at all? Why take all these elaborate precautions if there is nothing in any way dangerous to health in breathing sewer air? But were the researches and experiments hitherto made final? Did it necessarily follow that the absence from sewer air of all microbes contained in the sewage imply the harmlessness of such air? Now, the methods for the detection in liquids of the bacillus typhosus and other organisms had undergone great improvement since Parry Laws made his experiments, and they were still being perfected. Then as regards the harmlessness of sewer air, there were histories of numerous outbreaks of enteric fever, in which the most competent observers had expressed the opinion that the evidence irresistibly pointed to the cause being sewer and drain emanations. There was a mass of evidence in the hands of the medical profession that drain and sewer emanations are the cause of much illness. As regards human specific diseases, were they yet in a position to assert that it is the presence of the specific microbe that always determines the onset of the disease? At present they were only on the threshold of understanding the part microbes play in nature, and the trend of modern investigation gave more and more importance to the predisposing causes, and detract from the view originally held that the specific microbe was the be-all and end-all of diseases. Was not this particularly true of the part played in disease causation by dirt, overcrowding, dampness, drain and sewer emanations? A population living under ideally perfect sanitary conditions would have

little to fear from bacillary diseases. As Medical Officers of Health, they were entitled to say that the harmlessness of drain and sewer air had not yet been demonstrated; on the contrary, there had been much to show that the breathing of such air may be the determining cause of various illnesses. Under these circumstances, he thought they ought to insist on sewer gases being dispersed into the atmosphere in such a way as not to become a nuisance and injury. This involved the condemnation of roadway surface ventilation, but as openings must exist to prevent pressure into the houses, and for other reasons, the question was what openings should they have. He thought the desired results could be obtained by 6in. shafts conducted up the sides of houses, or by 6in. iron ventilating standards 20ft. to 30ft. in height, placed in the most open situations away from houses, or where necessary in the streets, placed on refuges like the electric light standards in the middle of the roadway. This method had been adopted in several provincial towns recently sewered, and the gases escaped well above the level of foot and carriage public. In narrow streets the danger of the gases escaping into the houses would be greater, but not greater than at present exists with surface gratings. He did not see what more could be done. Special ventilating fans, furnace draughts, and similar means had been shown over and over again to be impracticable. Sewer air deodorisation by charcoal and chemicals was of no avail, and sewer air cremation, he believed, had been abandoned. Of course, they would advocate the replacing of old sewers by sewers of modern construction, for nuisances arising from defective sewers could not be got rid of in any other way. To his mind, the interception of house drains is now inevitable, but twenty or thirty years ago a different system was possible, and would probably have answered better, but was rejected in deference to the then prevailing views of the infectivity of sewer gases.

The PRESIDENT said the question had been agitated for the last twenty years, but it did not get much further. He had always regarded sewer air as harmful. At Hampstead the sewers had been ventilated by means of pipes up the trees, but the cost was almost prohibitive.

Dr. F. J. ALLAN, Strand, referred to the attitude surveyors had taken on this question, which it was proposed should be discussed at a conference of Medical Officers and Surveyors. Sewers could be divided into two classes, local and main, and they required different treatment. If the local sewers were properly laid they would not want very much ventilation.

Dr. SIDNEY DAVIES, Plumstead, thought that what was required was more vent, not ventilation.

Dr. R. DUDFIELD, Paddington, remarked that the existence of what they called, for want of a better name, "drain throats," was a clear indication that sewer gas is not innocuous.

Dr. J. F. J. SYKES, St. Pancras, said that Medical Officers were agreed that sewer gas in the house is dangerous. The negative results of the researches up to the present time could hardly be accepted as binding. Anything which would drive sewer gas into the houses was not the right course to pursue; let it go into the streets, at any rate, where it was less dangerous. The reason why the County Council sewers were more nuisance than the local sewers was because they are only periodically wetted, in the meantime being dry and emitting horrible smells.

Dr. JACKSON, Fulham, having spoken,

Dr. PARKES replied to some of the points raised. He said that the most complaints came about the Council's sewers, and he thought that they ought to insist that the boundaries of London should not be further extended, for already stale and putrid sewage from other districts passed through large populations. Then some of the old flat-bottomed sewers still existed, and these ought to be abolished and proper sewers put in their place; indeed, he believed that in some cases the sewers had no bottoms, but simply carried the sewage along on the clay. He did not think it was possible to abolish the interceptors, because so many houses had been re-drained. The system must now go on, although many now agreed with him that there was not so much necessity for it, as the idea that sewer air contained germs of specific disease had been abandoned. But in respect of predisposing causes sewer gas was more dangerous than ordinary air.

Dr. DUDFIELD called attention to a published statement that the Government were about to appoint a Commission on the bacterial treatment of sewage, and moved a vote of thanks to Dr. Parkes for his paper, which was carried *nem. con*, and the proceedings terminated.

Sanitary Inspectors' Associations.

LONDON.

THE fifteenth annual dinner of the Sanitary Inspectors' Association was held with much success at the Holborn Restaurant on Saturday evening, the 19th inst., the President, Sir John Hutton, J.P., L.C.C., occupying the chair; being supported by Sir Walter Foster, M.P., Sir J. Crichton Browne, F.R.S., the Archdeacon of London, Mr. F. O. Crump, Q.C., Dr. H. Mansfield Robinson, LL.D, Professor Attfield, Mr. E. Lewis Thomas, Mr. J. Savage, Mr. E. Haward, Mr. Aubrey Richardson, Mr. J. T. Brown, Mr. J. T. Moss-Flower, Mr. C. T. Kingzett, F.I.C., Mr. P. Gates, Dr. Milsom Rhodes, Mr. A. Shand, J.P., Mr. C. W. Raymond (the hon. treasurer), Mr. T. G. Dee (the chairman of the Council), Mr. W. H. Grigg, Mr. W. H. Watson, Mr. D. Travis, Mr. H. Alexander, Mr. W. W. West, Mr. E. Tidman, C.E. (the hon. sec.), and a large number of members, the King's Hall being filled. During the evening a musical programme was carried out by Messrs. C. B. Macdona, G. Hope, J. H. Jenkins, F. E. Poucheron, and Mr. T. Best Folkes, Mr. Grasen Hope being at the piano. Grace was said by Archdeacon Sinclair, and after dinner the loyal and patriotic toasts were duly honoured, the latter being proposed by Sir CRICHTON BROWNE, and responded to by Dr. MANSFIELD ROBINSON.

Mr. AUBREY RICHARDSON gave "The Houses of Parliament," and in replying, Sir WALTER FOSTER, M.P., said the House of Commons had a great deal to do with the public health service, and he was sorry that by the last Local Government Bill Sanitary Inspectors were not all favourably affected. This, he thought, was a good reason why they should keep a vigilant watch on the proceedings of the House of Commons.

In giving the toast of the evening, "Success to the Sanitary Inspectors' Association," the PRESIDENT, who was received with loud cheers, said the year through which they had passed had been somewhat uneventful, but they had been able to keep together in a way which showed the Association was on a firm and substantial foundation. He thought this was due to the fact that they had not sought to limit the operations of the Association to London, large as London is, but had extended their organisation throughout the length and breadth of the land, having now a membership of 700. They hoped that the coming year would see a still further appreciation on the part of Local Authorities for the work of the Sanitary Inspector, because they could not forget the fact that among the four and a-half millions of people in London there were only some 200 Inspectors, who, capable as they were, without a doubt were totally inadequate to grapple with the needs of the city. Then, too, when they considered the fewness of the number of men engaged they were appalled at the poverty of the remuneration those men received. Out of the 200 Inspectors only nine received a salary above £200 a year, and there were 112 Inspectors who received below £150 a year. That was a totally inadequate remuneration for the services rendered, and he could assert that if they desired, as they all did desire, to attract to sanitary labour men of strict integrity and great ability, men with special learning for the discharge of special duties they could not hope to be successful until the remuneration for those gentlemen was on a higher scale. He felt this keenly, because the London County Council was under agreed circumstances obliged to pay a moiety of those salaries, and the Council was now considering as to whether it could not usefully take a stand in this matter by insisting upon Local Authorities increasing the remuneration of Sanitary Inspectors in order that the right class of men could be attracted to this branch of the public service. (Loud cheers.) It was said it took three years to make a soldier, whose highest aim was to take life; was it not a sad thing to think that no training whatever was provided for those whose occupation was not to take but to save life? He hoped to see the day when there would be a college for the education and training of future members of that Association, or, at least, that there might be founded special classes where the elementary principles of the science they followed could be taught. Perhaps the scheme for a Chadwick-Richardson foundation might be a step in that direction. Whatever their discouragements might be — and from the nature of things a Sanitary Inspector was bound to make enemies—he was sure they would go on striving after the public good. They must remember that their highest duty was to see right and justice done. In their hands were placed numberless lives of the poorest and most helpless of people, and the trust was a sacred one, which they should not lightly undertake or ignore. So long as their enemies were the wrong doers then by all means let them boast of having such enemies. He believed their hearts were in their work, and he judged this not only from the excellence of the work done under such diverse circumstances, but he judged it from the intelligent contributions to the literature. They had to deal with much poverty in this splendid, sorrowful, sinful city; they saw many scenes of degradation and of vice; let them regard themselves as those whose mission it is to alleviate pain, to save life, and to make life higher, better, and nobler, then with vigour and interest they would go on their way knowing they had done something towards the common good. (Loud cheers.) The toast was enthusiastically drunk, and the President then made a presentation of an illuminated address and a gold watch to Mr. C. W. Raymond, one of the founders of the Association and its hon. treasurer for fourteen years. He referred to the admirable self-sacrificing work of Mr. Raymond, and said the testimonial was a worthy mark of esteem and regard of his fellow members.

Mr. C. W. RAYMOND having suitably acknowledged the gift, the President made a second presentation, the recipient, Mr. W. W. West, being taken completely by surprise. He said that the members desired to mark their appreciation of the manner in which Mr. West had occupied the chair of the Council, and asked his acceptance of an illuminated address and a handsome writing case as evidence of the feelings entertained for him by the members of the Association. Mr. West having replied, Mr. E. Lewis Thomas proposed the toast of "Local Government," and Mr. A. Shand, chairman of the St. Olave's District Board of Works, responded. "Education" was toasted at the instance of Mr. F. O. Crump, Q.C., and the Ven. Archdeacon of London, in an amusing speech, which was well received, responded. Dr. Rhodes gave "Science and Art," and Professor Attfield acknowledged the toast, which was followed by that of "The President," appropriately submitted by Mr. Percy Gates, and it was drunk with great enthusiasm. Sir John Hutton having replied, the toast of "The Executive" was given by Mr. Crump, and Messrs. T. G. Dee, C. W. Raymond, and E. Tidman replied. Mr. C. T. Kingzett proposed "The Visitors and Guests," and Dr. Mansfield Robinson and Councillor Hudson, of East Ham, acknowledged the compliment, the toast of "The Press" was submitted by Mr. Macmahon, and in the absence of Mr. J. T. Brown, of THE SANITARY RECORD, who had to leave early, was replied to by Mr. Clarence E. Ady, the enjoyable gathering dispersing at a late hour.

MUNICIPAL OFFICERS' ASSOCIATION.—Alderman Sheriff Frank Green, in the absence of the Lord Mayor through indisposition, presided on Tuesday night in the Council Chamber, Guildhall, at the fifth annual meeting of the Municipal Officers' Association—an organisation admitting to membership officers of "any statutory Local Government Authority," which seeks, among other objects, "to secure adequate superannuation for its members," and considers Local Government questions, together with judicial decisions and proposed legislation relating thereto. Since the preceding annual gathering, it was reported, the membership of the Association, now nearly 1000, had trebled, and satisfaction was expressed at the steady increase in the number of members resident, not only in London, but in all parts of the country. The Lord Mayor was elected president, and the vice-presidents chosen included Mr. C. J. Stewart and Sir A. R. Binnie, of the London County Council. A discussion took place on the Superannuation Bills now before Parliament.

Institute of Sanitary Engineers

THE CHEMICAL EXAMINATION OF WATER.

By RICHARD HORTON.

(*Continued from page* 179.)

I will here give the analyses of the samples of water mentioned in the first part of my paper.

Sample of water from well near Tunbridge Wells :—

	Before cleaning.	After cleaning, &c.
Chlorine	2·2 grains per gallon	1·6 grains per gallon.
Free ammonia..	·04 parts per million	·026 parts per million'
Albuminoid ..	·29 ,, ,,	·074 ,, ,,

It will be seen that there could be no hesitation in condemning this water, which was justified by results of the second examination after cleansing.

Analyses of water from a well in North London, supposed to be 18ft. in depth, which was afterwards proved to be 68ft. deep :—

	My own examination.	The Public Analyst's.
Chlorine	·8 grains per gallon	1·4 grains per gallon.
Free ammonia..	·03 parts per million	0·000 parts per million.
Albuminoid ..	·07 ,, ,,	0·071 ,, ,,

The analyst's analysis was made a month after my own, and the ammonia was returned as grains per gallon, but has been calculated on the million by me for the purpose of comparison.

It is as well, perhaps, to make a simple test for poisonous metals, as follows :—Take two white glazed basins, each capable of containing 100 cubic centimetres. Into one basin pour 70 cubic centimetres of distilled water, and the other 70 cubic centimetres of the water to be tested ; dip a clean glass rod into a bottle of ammonia sulphide solution, and stir into the water to be tested with it ; treat the distilled water in a similar manner, using a clean rod. If either lead, iron, or copper is present the yellowish colour imparted by the sulphide will be blackened more or less according to the quantity of metal present. This colour, however slight, may be seen by comparing with the similarly treated distilled water. If a colouration other than the slight yellow colour should occur, it ought to immediately disappear upon adding a few drops of hydrochloric acid, indicating iron ; if it does not disappear lead or copper or both are indicated.

It would not be possible, in a short paper, to give full working directions for either of the processes touched upon, but I trust sufficient may have been included to induce those who think the chemical examination of water is wrapped up in mystery and difficulty to attempt the work experimentally, and I am assured that even should they not make a constant practice of it in their work, the knowledge gained will be invaluable to them in considering the reports of public analysts.

The whole subject is so interesting that at least to some the brief description of water analysis here given will be very inadequate. To those I can confidently recommend Wanklyn's "Water Analysis," which is written so simply that previous knowledge of chemistry is not necessary to understand every operation described, and, if further information is desired, Kenwood's "Public Health Laboratory Work" will, if purchased, not be regretted. The latter book includes an article on the bacteriological examination of water.

The CHAIRMAN asked if the lecturer in taking samples of water was always careful to put them in bottles or receptacles which had been cleansed ?

The LECTURER said that was very important. The glass bottle should first be cleaned out with acid and rinsed out with ordinary tap water. Hydrochloric acid he used—they must rinse it out until they could not taste it. Then they must put the stopper in and take a piece of clean linen rag and tie it over the bottle. When they took a sample of water they should rinse out the bottle several times with the water they had to test. They should fill the bottle two or three times and shake it about, and then fill it with the water to be tested, and put the stopper in. It was most particular that they should tie it down. If they were taking a sample from a well they must not take the contents of the pump, but pump until they had the water from the well. He was very glad the Chairman had asked that question.

Mr. FARLEY said he would like to refer to one particular fact. With regard to the outbreak at Maidstone, he did not know who made the bacteriological examination of the water, but it was said to be quite impossible to find any typhoid germs in the water, so that it seemed to point that an analysis of water was not to be relied upon under all circumstances. As far as he understood, there were two or three samples taken, and in none of them were any germs of typhoid found. That led them to the conclusion that the typhoid germs, so-called, could hardly be said to have been discovered. They knew that there were benificent and malignant germs. It was a question to him whether really the typhoid germ had ever been discovered. It was a very strange thing, but he believed at Worthing the same thing obtained. He had listened with very great interest to Mr. Horton's paper, and, of course, there was no doubt that an engineer should know something about water analysis, but at the same time he should not recommend any engineer to attempt analysis himself. All the operations were so delicate, and, of course, required a great deal of time. As a matter of fact, if an engineer's time was not more valuable than to spend it in the analysis of water he could not have much practice. An analyst had eight or nine samples of water around him which he could analyse at the same time, but if they, as engineers, took a sample of water, although they might know how to do it, they would find the time it would take would certainly trespass to a great extent upon their business. Of course analysis, as he had said, was valuable—very valuable—but at the same time it did not do to depend on it, and in country districts his recommendation, where water was at all suspicious, was to carefully boil it. The objection to boiled water was that it was insipid afterwards, but if they put it through a filter they could make it bright and sparkling again, although he did not recommend filters as such, with the exception that there was one at the present time which could be relied upon with certainty : that was the Pasteur-Chamberland ; and there was also another one as reliable—the Berkefeld. There was no doubt the Pasteur-Chamberland filter took out every germ known to science, but still at the same time if the water was allowed to stand after it had been through the filter the germs got there again and multiplied again. So unless they drank the water as soon as it came through there was still that

danger. He did not know whether he would be right in taking on himself to propose a vote of thanks to Mr. Horton, but he was sure their thanks were due to him for the very interesting paper he had read, and for the time and trouble taken by him on their behalf. It was a very interesting subject, but he was afraid in a paper of that sort it was somewhat difficult to follow it. At the same time it was a very interesting subject, and there was not the slightest doubt that with a small amount of practice a man could get fairly accurate results. He begged to propose a hearty vote of thanks to Mr. Horton.

Mr. WELLS said he had much pleasure in seconding the vote of thanks. He was sure he had listened with great pleasure to the explanation of the analysis which had been given them, and it would be a great benefit to them to read the paper at greater length when they got it in their RECORD, and could follow it better than they were able to do there that night. He was sure it would be an encouragement to all of them to try and follow out the experiment which they had been shown that evening.

Mr. CARTER said he could only re-echo the remarks of the previous speakers. He had listened with great interest, and although they could not all expect to follow it up in their own work, yet they might have some spare time, and he thought the paper which Mr. Horton had given them would be of benefit to themselves and the profession. He should certainly make an attempt himself to do it in a small way. He would like to know the cost of the book Mr. Horton had referred to.

Mr. HORTON said it was 5s. gross.

Mr. FARLEY said there was one thing very important to know in taking a sample of water, and that was that their bottle was clean, and that there should be a glass stopper. Very frequently in his little way he had samples brought in dirty old corked bottles. Water of that kind was of no use. The operation was so delicate that they must have sterilised bottles, and they must also be careful, if they were in a perspiration, that their fingers did not touch the stopper as they put it in. All those things were of great importance if they wanted to get a correct analysis, and he thought everyone who had to do with taking those samples should know those important points.

Mr. HORTON said that last matter was most important. He did not know whether they had missed his most important point. He did not propose to make an absolutely correct analysis of water, but simply to give an indication of the water, so that if they had water loaded with chlorine or ammonia, they might be tolerably certain they had pollution somewhere, and it had to be found out. That was what he tried to impress in his paper. If they discovered a large quantity of inorganic matter, that classed that water as undoubtedly dangerous for drinking purposes. Of course they could suggest boiling and filtering, and that kind of thing, but still he thought until they knew whether the water was pure or impure they would hardly recommend a person to boil the water. Honestly they could not. It would not have been fair to put the person using the well he had mentioned in the North of London to the trouble of boiling the water which turned out to be from a deep well and of better quality than ordinary London water, for the boiling would probably have spoilt the water. They wanted to be able to get an idea of the water in outlying districts, so as to advise or not that a sample should be thoroughly analysed by a competent analyst bacteriologically, although he thought in the present state of bacteriological knowledge it did not so much matter. As far as the Maidstone epidemic was concerned, he had read what Mr. Farley had stated himself, and he was rather amazed to find that the water showed no signs of bacteria, but that might be explained by the fact that the bacteria was not able to live in pure water, and if the water had been purified since the typhoid outbreak bacilli would have vanished. To have got a proper idea the analysis should have been made during the outbreak of fever. To analyse the water afterwards was not quite the same thing.

Mr. FARLEY: But you know they took it while it was going on, and there were several cases afterwards from the same water?

Mr. HORTON said it might not have been the same water, and the people would not take ordinary precautions, and they could not tell that frequent discharges were not observed by the people in the same villages—it was evident from the report in some cases. Still there was no doubt that the chemical analysis did give a very good idea of the quality of the water. As to whether it caused typhoid fever if drunk they could not say.

The CHAIRMAN: Your point is that your experiment would give sufficient indication if there was any serious pollution of the water?

Mr. HORTON: Yes; if there is anything at all.

Mr. FARLEY said if there was chlorides or chlorine there was evidence that there had been pollution, but it would not give the knowledge that it was still going on. A water with plenty of chlorine was a nice water to drink. They really wanted a thorough analysis before they could give a definite opinion with regard to any water.

Mr. HORTON: Yes.

Mr. FARLEY: You did not take a simple test for lead; that would have been useful.

Mr. HORTON said they did not get the quantities sufficient. They could take one-tenth of a grain by the way he stated.

The CHAIRMAN said he took Mr. Horton's paper as representing the advisability of sanitary engineers having the ability to test under certain circumstances, without suggesting that the sanitary engineer should make himself an expert on the subject. At the commencement Mr. Horton said the engineer at the present time was loaded with matters upon which he had to have a knowledge, and to extend his knowledge was adding an almost unnecessary burden. But he certainly came to the conclusion before the paper was finished that what was suggested was a very simple measure, and to those who had the time it was a means of very greatly aiding them in their business. Of course an engineer was not considered a water expert, and if he found even the slightest suspicion that the water was more or less foul his duty would be at once to send to an expert whose opinion would be taken and worked upon. A vote of thanks had been proposed to Mr. Horton for his certainly able paper. When they were able to give more time to study it they would be able better to appreciate the ability he had shown in giving them the means of themselves trying those simple tests, and thus extend the power of their research in sanitary

matters, because there was no doubt that water was one of the things they must all look to as being necessary for the health and well-being of mankind.

Mr. DAVENPORT said he would point out that it would be well if they were taking water from a well that note should be taken of the general surroundings, for when he took a sample to an expert he generally liked plenty of detail.

The motion was carried, and a similar compliment was paid the Chairman on the motion of Mr. WELLS, seconded by Mr. DAVENPORT.

General News.

NOTICE.—On and after 31st March next the Annual Subscription to this Journal will be raised to 12s. 6d. to all NEW Subscribers. NO ADVANCE will be made to our friends whose names are entered on our Subcription list prior to that date, so long as they continue to Subscribe.

STROUD.—It is proposed to erect an isolation ward for the workhouse.

PEWSEY.—The District Council is considering a scheme for supplying Pewsey with water.

CREDITON.—Application is to be made to the Local Government Board to borrow £550 for the new reservoir.

LEEDS.—The City Council is considering a recommendation to purchase the Oriental Baths, at a cost of £18,000.

CANNOCK.—The Rural District Council has decided to purchase a steam roller at a cost of £330, with sleeping car £63, and water cart £28.

WHICKHAM.—The Urban District Council is considering the advisability of abolishing the ashpit at Marley Hill, and of erecting privies in each house.

EDINBURGH.—The Town Council has approved of sketch-plans of public baths, including Turkish chambers, to be erected at Portobello, at a probable cost of £18,000.

CLACTON-ON-SEA. — At a private conference between the Urban District Council and the directors of the gas and water company it is understood that an agreement was arrived at for the immediate purchase by the Council of the company's undertakings.

MAIDSTONE.—The monthly report of Mr. A. Adams, Medical Officer of Health for Maidstone, shows that in the past four weeks twenty-nine deaths have been registered in the borough, constituting a rate of only 11·05. No fresh case of typhoid has been notified since January 31st.

KEMPSTON.—The School Board, at a recent meeting, decided to close a well in the yard at the Up-end Schools in consequence of the unfavourable analysis of a sample of the water which had been submitted to a public analyst by the Medical Officer of Health for the urban district. Several other wells have been tested with varying results. Some are reported as unsuitable for drinking purposes, and in others the percentage of organic matter is high.

ENFIELD.—The Local Government Board has recommended the Loan Commissioners to lend the Urban District Council £26,700 for a new isolation hospital.

DUMFRIES.—A new clear-water storage tank is to be constructed by the Dumfries and Maxwelltown Water Commission, at an estimated cost of £3000.

BACUP.—At the last meeting of the Town Council it was resolved that application be made to the Local Government Board for sanction to borrow a further sum of £4486 for the construction of new filters at Sheephouse, and £1034 for the purchase of the site.

ASHINGTON.—The County Medical Officer, Dr. Hembrough, has spent two days in inspecting the urban district of Ashington. He visited the dairies and cowsheds, and the source of the water supply down the pit, and after his inspection he strongly recommended the adoption of bye-laws.

MILDENHALL.—The ninth annual report of the Medical Officer of Health on the health and sanitary condition of the Lakenheath and Worlington districts of the Mildenhall union, during the twelve months ending December 31st, states that from a sanitary point of view the year was an uneventful one.

RIPLEY.—At the last meeting of the Urban District Council the clerk was instructed to write to the Public Works Loan Commissioners with reference to the loan of £1000, in order to enable the Council to carry out the water scheme. The surveyor advised that this work be done in sections, and tenders are to be invited.

NEWCASTLE.—The Tyne Port Sanitary Authority is fully alive to the importance of close supervision of all vessels arriving from the Tees. At a recent meeting of the Hospital Committee in Newcastle it was agreed to appoint a second Medical Officer, so that vessels might be at once brought under inspection by day or night.

HARROGATE. — Mr. Shiress Will, Q.C., the umpire in the recent arbitration, has fixed the price to be paid by the Corporation for the undertaking of the Harrogate Water Company at £187,000. The expert valuations handed in on behalf of the claimants amounted to about £242,800, and those for the Corporation to about £168,600.

GUISBOROUGH.—At a meeting of the Guardians recently the question of taking steps to meet any outbreak of small-pox in the district was considered. It was agreed that the public vaccination officers should make special visits to the various vaccination stations for a month for the purpose of performing free vaccination with calf lymph.

CUPAR, FIFE.—Mr. George White, Sanitary Inspector, recently submitted an able and exhaustive report as to the sanitary condition of the town to the Police Commissioners. It is stated that he had never had to make a complaint about the cattle market, which was cleansed regularly after the weekly sale. The whitewashing of the cattle trucks on the railway embankment was done thoroughly. The management of the common lodging-houses was all that could be desired. The dairies and milk stores were all cleanly kept, and he had had no complaints as to the quality of the milk supplied within the burgh.

ROCHDALE.—The report adopted by the Town Council states that the Corporation would require £44,200 for the mains, pipes, monopoly of water—present and prospective value.

EASTBOURNE.—The Town Council has resolved to make an installation of the Reeves system at a few of their worst manholes in order to prevent further complaints of nuisance from these manholes.

MIDDLESBROUGH. — The small-pox outbreak appears to have been overtaken by the Authorities. The spread of the disease appears to have been checked, and it is now hoped and believed that it will not be necessary to utilise the new lunatic asylum as a small-pox hospital. The erection of temporary structures for the accommodation of small-pox cases is now being proceeded with as rapidly as possible.

WEST HAM.—At a recent meeting of the Urban District Council, the following resolution was, after a very uproarious scene, carried:—"That all female Sanitary Inspectors hereafter appointed by the Council shall receive the same salary, with the same increments, hold the same position, and be liable to perform the same duties—as far as difference of sex will allow—as the then last appointed male Sanitary Inspector."

MANCHESTER.—The improvement of Manchester thoroughfares and the development of the electric lighting undertaking of the Corporation formed the subject of a Local Government Board inquiry last week. The Corporation applied for a Provisional Order empowering it to borrow money for the purpose of making a new street from the junction of Long Millgate and Ashley-lane to Charter-street, and for the widening of Hanging Ditch; for sanction to borrow £16,000 for the electric lighting of the city, and £10,000 for the provision of sanitary conveniences.

Personal.

MR. W. P. JONES, Swansea, has been appointed surveyor for the Glyncorrwg urban district.

DR. S. A. SHIACH has been appointed Medical Officer for the Llanishen district of Cardiff union.

MR. W. J. NICOLL has been appointed Medical Officer for the fourth district of Chipping Norton union.

MR. A. A. BLAKISTON has been appointed Medical Officer for the fourth district of Shepton Mallet union.

MR. M. DUNN, of Selby, has been appointed gas manager for Goole, at a salary of £300 per annum.

T. G. EMERSON, M.D., has been reappointed Medical Officer of Health for the urban district of Wantage.

W. A. E. HAY, M.R.C.S., has been reappointed Medical Officer of Health for the rural district of Bridport.

MR. R. K. HAMILTON has been appointed Medical Officer for the Hasland district of Chesterfield union.

C. J. BENNETT, M.R.C.S., has been reappointed Medical Officer for the Hayfield Rural District, and Parish Councils.

W. T. DAVIES, L.R.C.P., M.R.C.S., has been appointed Medical Officer for the second and third districts of the Hertford Union.

H. W. ARBUCKLE, M.D., D.P.H., has been reappointed Medical Officer for the Stamforth sanitary district of the Thorne Union.

MR. THOS. GEORGE TAYLOR, C.E., Borough Surveyor of Douglas, has been appointed Surveyor for the town of Ramsgate, out of a large number of candidates for the post.

MR. J. W. WYNNE, who has been manager of the Milnthorpe gasworks for over two years, has been appointed to the secretaryship and managership of the Ambleside gasworks.

DR. WALTER E. JAMES, Abercarn, who holds the appointment of Medical Officer to the Abercarn Urban District Council, Magor Rural District Council, and St. Mellon's Rural District Council, has been elected Medical Officer and public vaccinator for the parish of Mynyddislwyn, in succession to Dr. W. H. Davies, J.P., retired.

Sewerage Schemes.

[TO MUNICIPAL ENGINEERS AND SURVEYORS.—The Editor will be pleased to receive items for publication relating to sewerage schemes projected or inaugurated, together with explanatory diagrams or photographs. The former should be drawn and lettered in black ink.]

SANCTION for the extra sewerage loan of £1196 for East Molesey has been obtained.

THE Local Government Board has sanctioned the borrowing of £5000 for sewerage purposes at Wokingham.

A LOCAL Government Board inquiry has been held at Batley concerning an application of the Town Council for sanction to borrow £13,494 for works of surface-water drainage.

THE Local Government Board has sanctioned the borrowing of £16,500 for the purchase of land for the sewage purification scheme at Morley, and of £25,630 for the construction of the works.

THE Local Government Board has sanctioned the application of the Hendon Rural District Council to borrow £2200 for works of sewerage and sewage disposal in the parish of Great Stanmore.

A LOCAL Government Board inquiry has been held with reference to an application by the Winchester Rural District Council for permission to borrow £5000 for the purpose of carrying through a sewerage scheme for the parish of Bishopstoke.

THE Local Government Board has suggested certain alterations in reference to the Heysham sewerage scheme, which will increase the cost to £1500 from £1300. The Surveyor to the Lancaster Council has been instructed to obtain tenders.

A COMMITTEE of the Kent County Council recently recommended that the state of Chatham, which was still without a sewerage system, should be represented to the Local Government Board, but the Council deferred the matter for another year.

AT the last monthly meeting of the Benwell and Fenham Urban District Council, the Surveyor (Mr. Pattison) presented a special report as to the drainage of Benwell Towers. After detailing the tests he had applied and the results, he said the whole of the drainage system was faulty.

A COMMITTEE of the St. Faith's District Council was appointed recently to investigate into the reported polluted condition of a small stream which enters the main river about two miles above the intake of the Norwich waterworks, at Drayton. The investigation made was a searching one, and a report will be presented to the Council after the Committee has met.

ON Tuesday afternoon, the 15th inst., the foundation-stone was laid of the Sheffield pumping station works, in connection with the Walsall Wood sewerage scheme, which is being carried out by the Brownshills Urban District Council. The cost of the engineering works is about £11,700, and the population of the district served by the system is between 6000 and 7000.

A LOCAL Government Board inquiry has been held into a petition by the Rural District Council of Tadcaster for a Provisional Order to empower the Council to put in force with reference to certain lands required by it for the disposal of the sewage of the townships of East Tadcaster and West Tadcaster, the powers of the Land Clauses Acts, with respect to the purchase and taking of lands otherwise than by agreement.

A SPECIAL meeting of the Ilford Urban District Council was held last week with reference to the proposed sewerage scheme, when the approval of the Local Government Board was received of the scheme prepared by Mr. Santo Crimp, for the improvement and enlargement of the sewage works at Water-lane, and also sanction to a loan of £8000 for carrying out the works. The Clerk was directed to instruct the engineer, Mr. Crimp, to at once prepare the contract, drawing, specification, &c., and then to advertise for tenders for the said works.

AT the last meeting of the Farm and Sewage Purification Committee of the Sutton (Surrey) Urban District Council, an important report on the working of the bacteria filters from their commencement up to December 31st, 1897, was presented by Mr. C. Chambers Smith, C.E., M. San. Inst., Engineer and Surveyor to the Council, with plans, estimates, and a report recommending the adoption of additional coarse grain and fine grain bacteria filters of sufficient capacity to treat the whole of the sewage flow of the town. The Committee recorded on the minutes their high appreciation of the valued report, and decided to determine upon the extensions at their succeeding meeting.

THE Lichfield Rural District Council has received sanction from the Local Government Board to raise a loan to carry out the sewage scheme of drainage and sewage disposal for Chasetown, prepared by Mr. Edward Ives, C.E., of Derby. The Council's original scheme embraced the "Septic" system of sewage disposal, but the Local Government Board refused to entertain the idea of a loan. The disposal system now sanctioned is the "Universal," and the passing of the effluent over land.

THE Government has decided to immediately appoint a Royal Commission to inquire into the bacterial treatment of sewage. This important decision, which up to the present moment has, for no obvious reason, been kept a profound secret, has been arrived at on account of the pressure brought to bear by influential sanitary authorities, who are unable to comply with the Local Government Board's requirements as to the provision of what is officially deemed suitable and sufficient land for sewage disposal purposes. The remarkable success of the experiments at Exeter, Leeds, Sutton, and other towns have also moved the Government to action.

A SPECIAL meeting of the Ludlow Town Council was held recently to receive the report of the Sanitary Committee on the result of the recent conference between a deputation from the Ludlow Rural district Council and the Sanitary Committee of the Sewerage of East Hamlet and Ludford, and to make the necessary orders thereon. The Committee reported that it cannot see its way to recommend the Town Council to allow the Rural District Council to connect the sewers of these districts with the sewers belonging to the town, so that the sewage could be dealt with by the Town Council in a general scheme of sewage disposal, unless the borough boundaries be so extended as to include these districts within them.

Lighting.

THE gas manager of the Johnstone Corporation is of opinion that £15,000 is necessary to enable the gasworks to cope with the demand for illumination.

THE contracts for the generating plant in connection with the electric lighting scheme for the burgh of Leith have been accepted by the Corporation, and the work is now in hand.

THE annual report of Dr. Simpson, Medical Officer of Health for Perth, says that seemingly a new source of ill-health had arisen through their filthy gas. There probably had never been a more widespread and general complaint about anything, nor with greater reason, than there had been about the quality of the Perth gas. The smell that emanated from it on burning had been simply abominable. That it had been a nuisance, not only dangerous, but actually injurious, to health all over the town for the whole year had been abundantly proved by the prevalence of sick headaches and other evidences of loss of health caused by it.

AT a recent meeting of Portsay Police Commissioners it was explained that the sheriff had now authorised the adoption of the Gas Supply Act, and on the motion of the provost a committee was appointed to inquire and report as to the terms on which the present gasworks could be acquired.

CIRCULARS protesting against the proposal of the Gas Light and Coke Company to increase the price of gas have been issued by the Clerkenwell Vestry and the Holborn District Board of Works, and these bodies have also invited the other vestries affected to make a similar protest.

A LOCAL Government Board inquiry has been held to hear evidence of those interested in the application of the Selby Urban District Council, praying that a Provisional Order might be granted to it under the Gas and Waterworks Facilities Acts, and the Public Health Acts, to enable it to undertake certain extensions and improvements to the gasworks plant now owned by the Urban Council.

A SPECIAL meeting of the Hackney Vestry was held last week for the purpose of rescinding resolutions passed by the late Board of Works and also by the Vestry in regard to the subject of electric lighting in Hackney and also the dust collection of the parish, and to take into consideration the report of the Joint Committee of the Public Health and Electric Lighting Committees in reference to the advisibility of transferring the Electric Lighting Order to private persons or retaining the same.

THE ceremony of cutting the first sod in connection with the building of the new gasworks for Carluke and neighbourhood was performed by Mr. Alexander Pillans, J.P., on Monday, the 14th inst., on the site which has just been feued at Law Crossings. Mr. Pillans was asked to break the ground, which he did, and afterwards wished success to the undertaking, the company, and the contractors, and hoped the new work would be as beneficial to the company as it would be a boon to the community at large.

THE Gas and Electric Lighting Committee of Aberdeen Town Council recently had a conference with Professor Kennedy, London, on the question of the extension of the electric lighting system in the city. He expressed the opinion that the committee should not erect a sub-station, as he was convinced that the system could be more economically managed from one centre. He was glad that the committee proposed to extend the mains to the west end of the city, because, as it was a high-class residential district, it should pay well. With regard to the erection of destructor works for the utilisation of city refuse in the generation of electricity, he was of opinion that that was a matter worthy of careful consideration, and that the experiment might be attended with considerable success. The committee accepted the offer of Messrs. Mather, Platt, and Co., Salford, to supply a new 650-horse power engine and dynamo for £4147.

AT a recent meeting of the Gas Committee of the Hull Corporation, a letter was read from the chairman and secretary of the British Gas Company in Hull, whereby it was decided to supply gas to the Corporation for the area of the Kingston Gas Company, which had been purchased by the Corporation at 1s. 6d. per 1000 cubic feet. The Kingston Gas Company's price was 3s. per 1000, and the Corporation will re-sell to consumers at 2s. 8d. per 1000 cubic feet, so that consumers will at once get the benefit of the difference.

A LOCAL Government Board inquiry has been held at Haworth to investigate the District Council's application for a Provisional Order under Section 303 of the Public Health Act, 1875, varying the Haworth Act, 1872, as amended by a confirmation Act in 1880. The powers sought were threefold, viz.:—(1) "To hold and use for any purposes of the gas undertaking" 270 square yards of land adjacent to the gasworks recently bought from Messrs. John and Fred Brown at a cost of £38 5s.; (2) to "erect, alter, and maintain" such buildings on the land as may be thought necessary; (3) to borrow £2500 for extensions.

Notes and Queries.

[Subscribers have the privilege of obtaining advice in this column on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed to THE EDITOR, "Notes and Queries," THE SANITARY RECORD, 5, Fetter-lane, London, E.C.]

NOTE.—If an answer be required immediately, a stamped addressed envelope must be enclosed, when we will endeavour to furnish a copy of the answer by post, as owing to the large number of queries received we cannot guarantee the insertion of a reply in the succeeding issue.

972.—SMOKE TEST MACHINE: NAME OF MAKE REQUIRED.—"A. S. J." writes:—"Would you be good enough to give me a few particulars of the 'Crow's Nest' smoke-generating apparatus? I have not seen the advertisement recently, so am unable to discover the method of working."

Answer.—We regret we are unable to oblige our correspondent with the information, as we do not know of the machine referred to. If any of our correspondents can furnish us with any particulars relating to it, we shall be pleased to describe it in a subsequent number.

973.—SANITARY INSPECTORS: STATISTICS REQUIRED.—"M. B." writes:—"Would you please oblige me with information on the following points:—(1) Is a Sanitary Inspector's life, considered from an insurance point of view, a first, second, or third-class life? (2) What is the death-rate among Sanitary Inspectors, and what comparison does it bear with that of other trades, businesses, or professions? (3) Can you give cases in which Sanitary Inspectors, disinfecting attendants, &c., have been known to contract infectious disease in the execution of their duty? (4) Also cases in which Sanitary Inspectors, disinfecting attendants, &c., have been known to carry infectious disease to their families?"

Answer.—(1) We regret we are unable to furnish the information. The practice of insurance companies varies in respect to classification; but if our correspondent were to communicate with a few insurance companies, he would, no doubt, be able to obtain the information. (2) We are not aware that any statistics have been published giving the death-rate among Sanitary Inspectors. (3) We are unable to do so. Doubtless there are, however, many such cases, as there are in the

medical and nursing professions, whose members are brought, similarly to the Inspector, in contact with infectious cases; but with proper precautions the risks are not so serious as are anticipated by many people. (4) Such information might be procurable by communicating with the Chief Sanitary Inspectors throughout the country, who would no doubt be able to furnish many cases. We know of no other method by which our correspondent could obtain the desired information.

974.—Municipal Corporations Act: Member Interested in Contract.—"R." writes:—"Will you kindly inform me if it is legal for a member of the Corporation to purchase iron manhole covers from the Corporation, and sell them to another tradesman in the town?"

Answer.—It is provided by Sec. 12 of the Municipal Corporations Act, 1882, that a person shall be disqualified for being elected, and for being a Councillor, if and while he has, directly or indirectly, by himself or his partner, any share or interest in any contract or employment with, by, or on behalf of the Council. We are of opinion that in such a case as that named by our correspondent a Councillor would be interested in a contract with the Corporation within the provisions of the section referred to, and that he would also render himself liable to a penalty of £50, as provided by Sec. 41 of the Act. An action to recover the penalty may, however, as defined by Sec. 224, only be brought by a burgess of the borough, and will not lie unless the plaintiff, within fourteen days after the cause of the action arose, served a notice in writing, personally on the person liable to the fine, of his intention to bring the action, nor unless the action is commenced within three months after the cause of action arose.

975.—Petroleum Acts: Local Authority.—"U. S. D." writes:—(1) "Will you please name the latest Act of Parliament regulating the keeping and sale of petroleum? (2) What is the definition of the term 'petroleum'? (3) Who are the proper Local Authority for the granting of petroleum licences within an Urban Sanitary District not being a borough? (4) Is it the duty of the Sanitary Inspector of an Urban Sanitary District to inspect petroleum stores, and take and test samples? (5) Where can the necessary testing apparatus be obtained?"

Answer.—(1) The Acts in force relating to petroleum are The Petroleum Act, 1871, The Petroleum Act, 1879, and the Petroleum Hawkers' Act, 1881. (2) The term "petroleum" is defined by Sec. 3 of the Petroleum Act, 1871, to include any rock oil, Rangoon oil, Burmah oil, oil made from petroleum, coal, schist, shale, peat, or other bituminous substance, and any products of petroleum, or any of the above-mentioned oils. (3) By Sec. 27 of the Local Government Act, 1894, district councils, whether urban or rural, are invested with the execution as the Local Authority of the Acts relating to petroleum. (4) Not unless he is duly authorised by the Local Authority as provided by Sec. 11 of the Petroleum Act, 1871. (5) Petroleum testing apparatus, for testing the flashing point of illuminating oils (Sir Frederick Abel's Government pattern as supplied to the Government Inspectors under the Petroleum Act, 1879,), may be obtained from the manufacturers, Messrs. Negretti and Zambra, Holborn Viaduct, London, E.C.; the price of the apparatus complete in box, for use with oil only or gas only, as may be preferred, £6 10s.

976.—Ambulance Carriages: Makers of.—"W. M." writes:—"We should be much obliged if you would kindly furnish us with the names of makers of ambulances such as would be suitable for a village."

Answer.—The following firms are manufacturers of ambulance carriages, viz.:—Messrs. Wilson and Stockall, County Ambulance Works, Bury, Lancashire; Messrs. Atkinson and Philipson, 27, Pilgrim-street, Newcastle-on-Tyne; Mr. Alfred Carter, Limited, Holborn Viaduct, London, E.C.; the Bristol Carriage and Wagon Company, Bristol; Messrs. Chalmers and Company, High-street, Redhill, Surrey. The St. John Ambulance Association, St. John's Gate, Clerkenwell, London, also supply and advise as to the construction of ambulance carriages.

977.—Inspectors of Factories: How Appointed.—"F. H." writes:—"I should be greatly obliged if you would inform me what steps I must take to become one of her Majesty's Inspectors of Factories. Is there any age limit? How often do vacancies occur? I should be glad if you can supply me with any information bearing on the appointment, such as duties, hours, salaries, &c."

Answer.—Appointments of Inspectors of Factories and Workshops are not open to competition. By Sec. 67 of the Factories and Workshops Act, 1878, the appointment, payment, &c., of such Inspectors, and their assistants, clerks, &c., is assigned to a Secretary of State—in this case the Secretary of State for the Home Department. Possibly, if our correspondent were to communicate with her Majesty's Chief Inspector of Factories, whose address is Home-office, Whitehall, London, S.W., he might be able to obtain the particulars required.

978.—Settling Tank: Defect in: How to Remedy.—"One in the Dark" writes:—"I have had a settling tank constructed, the bottom of which is formed with 5in. of granite slag and cement. Underneath the concrete are rubble stones. The bottom is above the surface of the ground. The tank will hold water until about three-quarters full, when it will begin to leak very rapidly until it is all run off within about 9in. Could you please tell me what I should do to make it hold water?"

Answer.—It would appear that the bottom of the tank is of insufficient strength to withstand pressure of liquid beyond a certain depth. It is also very probable that, if the tank has been constructed on "made" ground, or partly "made" and partly natural, that a crack exists in the bottom. The remedy will be to increase the strength of the bottom by increasing the thickness to 12in., and this should be done in concrete, mixed in the following proportions and well rammed after being deposited, viz.:—Two parts granite, broken to pass through a ¾in. ring, one part clean sharp sand, and one part Portland cement. Before the concrete has had time to set, the surface should be rendered with neat Portland cement mixed with water to make a stiff mortar, and applied with a plastering trowel and hand float, so as to work the cement into all the crevices of the concrete, but leaving no body or coat of cement on the surface. The steel plastering trowel is then used to give it a smooth surface, and the operation is then complete. We may add that it will be advisable to pick off the cement rendering on surface of wall to a height of 2in. or 3in. above the intended new floor level, so as to give a "key" for the new work, and the angles between floor and vertical walls must be splayed in cement.

979.—The Ducat Filter for the Treatment of Sewage.—"Surveyor" writes:—"I am a selected candidate for the office of Surveyor to appear before a Council which has decided to adopt Colonel Ducat's system of sewage purification. Will you be good enough to explain the principle and method of the system, as I may be questioned with reference to it?"

Answer.—The Ducat filter, which is at work on a small scale at Hendon, is one which is worked on the continuous flow principle. It is constructed above the surface of the ground, with concrete floors and with walls constructed of 3in. agricultural drain tiles and brick piers about 8ft. apart. Along the floor of the filter, and at every 2ft. in height and 1ft. apart, are also laid rows of drain tiles communicating with the open sides, in order to

introduce air to all parts of the filter. The total depth of the filter is about 8ft., the filtering material being gravel or coke arranged in layers, varying in degrees of fineness, the coarsest material being at the top of the filter and the finest at the bottom. The sewage is distributed evenly in a fine film over the whole surface of the filter, at the rate of 200 gallons to the square yard per day, and it passes through the breeze and reappears in an open channel formed all round the base of the filter. The filtrate is claimed to be a very satisfactory one. Particulars of the Ducat and other filters will be found in Spinks' "House Drainage Manual," price 5s.

980.—ABNEY'S REFLECTING CLINOMETER: USE OF.—"J. M." writes:—"Is Abney's reflecting clinometer level suitable for use in place of a Dumpy level, for taking levels for the preparation of plans and sections for drainage or water supply works? I understand the instrument is much cheaper and more convenient for carrying about, and otherwise suitable for anyone who only uses a level at intervals and over comparatively short distances. An illustration of your own as to its use, or any other hints or advice, will be appreciated."

Answer.—Abney's clinometer is not suitable for use in drainage work, where absolute accuracy is indispensable. The instrument is convenient for obtaining angles of acclivity or declivity. Descriptions of the mode of construction and working of this and other surveying instruments will be found in Usill's "Practical Surveying," price 7s. 6d., or Stanley's "Surveying Instruments," price 7s. 6d. The former book will be found valuable to our correspondent.

981.—NUISANCE FROM KEEPING PIGS.—"T. W." writes:—"An owner of nine houses rented a plot of land on the opposite side of the back street for his tenants. In this land one or two of his tenants kept pigs. About twelve months ago the Sanitary Authority complained of the pig-keeping as being a nuisance, owing to the styes not being drained, whereupon the owner of the houses constructed the drains, and the Urban Sanitary Authority were satisfied. This week, however, the owner has received a notice from the lord of the manor to give up the land which he sublets to his tenants, through the Sanitary Authority describing this enclosure as a nuisance. Now is it in order for the Sanitary Inspector to get the lord of the manor to give notice to this man to give up the land? The Sanitary Inspector has not given any notice of a nuisance to the owner of the houses, nor has he reported the matter to his Authority."

Answer.—The information before us is not sufficient for us to properly advise. Our correspondent does not show conclusive proof that the notices served by the lord of the manor are in consequence of a complaint made to him by the Sanitary Inspector. But even if such a complaint had been made by the Inspector, we do not see how his action can be considered "out of order." He would, in our opinion, be acting properly in the discharge of his duties.

Contracts Open.

The dates given below are the latest up to which tenders can be received.

ARDSLEY (NEAR BARNSLEY). — February 26th. — Scavenging.—Mr. Thomas Harper, surveyor, Stairfoot.

BAMBER BRIDGE (LANCS).—February 26th.—Night-soil —The Council Offices, Bamber Bridge.

BRENTWOOD (ESSEX).—February 28th.—Scavenging. —Mr. C. Edgar Lewis, clerk, Brentwood.

CHASE TOWN (LICHFIELD, STAFFS).—February 28th-March 9th.—Mr. E. W. Ives, C.E., 20, Albert-street, Derby.

RAWMARSH.—February 28th.—Removal of Night-soil, &c.—Mr. J. W. Bellamy, clerk, Council Offices, Rawmarsh.

WINCHESTER.—February 28th.—Re-draining.—Mr. W. J. Taylor, county surveyor, The Castle, Winchester.

HALIFAX.—March 1st.—Sewer.—Mr. F. Gordon, Engineer's Office, Clifton, Brighouse.

SHOEBURYNESS.—March 1st.—Removal of Refuse.—Mr. W. Stafford, High-street, Shoeburyness.

WATERLOO (LANCS).—March 1st.—Scavenging.—Mr. F. Spencer Yates, A.M.I.C.E., surveyor of the Council, Town Hall, Waterloo.

GRAYS (ESSEX).—March 2nd.—Sewer.—The Council Offices, 49, Windmill-street, Gravesend.

WATFORD.—March 2nd.—Sewers.—The Council Offices, 14, High-street, Watford.

WATFORD.—March 2nd.—Sewer Pipes, &c.—The Engineer's Office, 14, High-street, Watford.

KING'S LYNN.—March 2nd.—Sewers.—Mr. E. J. Silcock, C.E., borough engineer, King's Lynn.

LITHERLAND (LANCS).—March 2nd.—Removal of Nightsoil.—Mr. W. B. Garton, surveyor, Public Offices, Sefton-road, Litherland.

OLDHAM.—March 2nd.—Sewers, &c.—Mr. S. A. Pickering, A.M.I.C.E., borough surveyor, Oldham.

GAINSBOROUGH.—March 3rd.—Sewer.—Mr. Henry Riley, engineer and surveyor, Council Offices, Gainsborough.

DARTON (NEAR BARNSLEY).—March 5th.—Scavenging. — Mr. James Gibson, clerk, Post-office-chambers, 5, Regent-street, Barnsley.

ANTISEPTIC

DISINFECTANT.

DEODORANT.

INODOROUS DISINFECTION.

Absolutely Non-Poisonous, Non-Corrosive, Non-Volatile, and does not Stain.

See published Bacteriological Report by Dr. E. KLEIN, St. Bartholomew's Hospital, London.

CHINOSOL SANITARY TABLETS are the most convenient, most effective, and most economic for the immediate production of Disinfecting Fluids. **12 Tablets**, packed in one tin to carry in waistcoat pocket, price **2s.** One Tablet in warm or cold water produces in **less than one minute**:—

3 Quarts of a strong Deodorant and Disinfectant, sufficient to spray one infected room of 1000 cubic feet; or

3 Gallons of a strong Disinfectant for flushing drains, walls, floors, &c.

Literature (Dr. Klein's Report) and Samples free to the Profession.

B. KÜHN, 36, ST. MARY-AT-HILL, LONDON.

Telegraphic Address: "CARMINES, LONDON." Telephone: Avenue 5976.

Vacancies.

BOROUGH SURVEYOR AND ENGINEER (MORLEY, February 26th).—For the Town Council. Salary, £200 per annum. Mr. R. Borrough Hopkins, town clerk, Town Hall, Morley.

BUILDING INSPECTORS (CROYDON, March 3rd).—For the Council. Salary, 50s. per week, with biennial increments of 5s. per week, until a maximum of 60s. per week is attained. Application forms to be obtained at the Borough Surveyor's Office, Town Hall, Croydon.

CLERK OF WORKS (PENISTONE, YORKS).—For the Urban Council. Clerk, Urban District Council, Penistone.

SURVEYOR, &c. (KNARESBOROUGH, February 28th). For the Urban District Council. Salary, £60 per annum for the surveyorship and £40 per annum for the inspectorship. Total salary, £100 per annum. Mr. Thomas Mainman, clerk, Council Offices, Knaresborough.

SURVEYOR (SHANKLIN, March 1st).—For the Urban District Council. Mr. J. Marsh, clerk, Council Chambers, Shanklin, I.W.

SURVEYOR (STAINES, February 28th).—For the Rural Council. Salary, £200 per annum, to include all travelling expenses. Mr. John Anthony Engall, clerk, Clarence-street, Staines.

SANITARY INSPECTOR (LONDON, W.C. (March 8th). For the Holborn Board of Works. Salary, £120 per annum. Mr. Matthew H. Hale, clerk, Holborn Town Hall, Gray's-inn-road, W.C.

SURVEYOR (LONDON, W., March 7th).—For the Vestry of St. Marylebone. Salary, £600 per annum. Vestry Clerk, Court House, Marylebone-lane, Oxford-street West.

COMPETITIONS.

WINCHESTER, March 31st.—Public Baths. Extension of Time.—The time for submitting plans for the public baths competition is extended to March 31st. Premiums of £25 and £15 will be awarded for the designs adjudged by the Council of sufficient merit, and placed first and second in order respectively. The premiated plans will become the property of the Corporation. Drawings and detailed estimate to be deposited at the office of Mr. Walter Bailey, town clerk, Guildhall, Winchester, marked "Swimming Baths," on or before March 31st, instead of 28th inst., as previously mentioned.

To Surveyors, Sanitary Inspectors, &c.—First-class Cycles at reasonable prices. Don't place your orders elsewhere until you have seen our post-free catalogue.—MELROSE CYCLE COMPANY, Coventr

DRUGS

WON'T DO.

FREE TRIAL OF SOMETHING THAT WILL DO.

You would be perfectly astonished if you were made aware of the many thousands of pounds absolutely thrown away from year to year upon so-called curatives that are foisted upon a public only too willing to believe the specious arguments laid before them.

Now, strength and muscular activity, rosy cheeks, plumpness and health, can be obtained without medicine.

It can be accomplished with a perfect, flesh-forming, palatable, and agreeble Food Beverage.

DR. TIBBLES' Vi-Cocoa

is such a Food Beverage, possessing, as it does, wonderful nourishing, strengthening, and stimulative powers unsurpassed by any other Food Beverage. Dr. Tibbles' Vi-Cocoa is not a medicine. It does simply what it is claimed to do, and its strengthening powers are being recognised to an extent hitherto unknown in the history of any preparation.

Merit, and merit alone, is what we claim for Dr. Tibbles' Vi-Cocoa, and we are prepared to send to any reader who names this journal (a postcard will do) a dainty sample tin of Dr. Tibbles' Vi-Cocoa free and post paid.

Dr. Tibbles' Vi-Cocoa, 6d., 9d., and 1s. 6d. It can be obtained from all Grocers, Chemists, and Stores, or from Dr. Tibbles' Vi-Cocoa, Limited, 60, 61, and 62, Bunhill Row, London, E.C.

IMPORTANT ANNOUNCEMENTS.

WILL SHORTLY APPEAR IN THE

Sanitary Record

A SERIES OF ARTICLES

ENTITLED—

"THE CHEMICAL AND BIOLOGICAL EXAMINATION OF WATER,"

BY

C. G. MOOR, M.A., F.C.S.

These Articles, which have been expecially written for THE SANITARY RECORD by Mr. Moor, will be fully illustrated, and will embody the results of the latest researches on this all-important subject.

The writer holds a unique reputation as joint author (with Mr. T. H. Pearmain) of "Applied Bacteriology" and "Aids to the Study of Bacteriology," both of which works have received high encomiums from the *Lancet*, the *British Medical Journal*, the *Chemical News*, &c., and we have no hesitation in commending this new series to the notice of all Public Bodies who are interested in the purity of public water supplies.

A

New Series of Articles

BY

W. J. DIBDIN, F.I.C., F.C.S.,

Late Chemist to the London County Council, Author of "The Purification of Sewage and Water," &c.,

WILL COMMENCE IN

The Sanitary Record

AT AN EARLY DATE.

Mr. Dibdin has chosen for his subject—

"LIME MORTAR AND CEMENT: Their Composition and Analysis,"

And the Articles will prove invaluable to Surveyors, Municipal Engineers, &c.

The date of publication will be duly announced in this column.

NOTICES.

ANNUAL SUBSCRIPTIONS. — *The Annual Subscription to "The Sanitary Record," paid in advance, is* 10s. *This includes postage, and a Copy of the Diary, post free.*

SUBSCRIBERS RESIDING in SCOTLAND and IRELAND are requested to pay by P.O. and NOT *by cheque. If cheques* BE *sent they must be drawn for* 10s. 6d

MSS. cannot be returned unless accompanied by a stamped directed envelope.

Advertisements cannot be inserted unless received before Four o'clock on the TUESDAY of each week.

All communications should be addressed to the EDITOR, at 5, *FETTER LANE, London, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, Ld.*

NOTICE.—On and after 31st March next the Annual Subscription to this Journal will be raised to 12s. 6d. to all NEW Subscribers. NO ADVANCE will be made to our friends whose names are entered on our Subscription list prior to that date, so long as they continue to subscribe.

THE

Sanitary Record,

MARCH 4, 1898.

Notes.

Local Government for Ireland.

THE long-looked-for has come at last, and Ireland is now in a fair way to obtain a system of local government, similar to that which has met with such success in England and Scotland. The Government Bill, introduced into the House of Commons last week

by Mr. Gerald Balfour, was received on all hands with a chorus of approval that augurs well for its future. It is impossible in this place to give even the barest outline of the numerous provisions of this comprehensive measure; but those of our readers who are concerned with Irish local administration have doubtless acquainted themselves with the substance of the new proposals from other sources. In its main features the Bill follows on the lines of the English and Scotch Acts, with such modifications as are required by the peculiarities of the existing system in Ireland, withdrawing the control of local affairs from nominated bodies, and entrusting it to bodies popularly elected.

The Administrative Bodies.

There will be no Parish Councils, as the parish has never been in Ireland an area of local administration; but there will be County Councils, Urban District Councils, Rural District Councils, and Boards of Guardians, to which the powers and duties of the existing bodies will be transferred. The County Councils are to have certain powers of veto over expenditure initiated by the Rural District Councils, which will accordingly have the right of representation on the County Councils. The general powers of both kinds of bodies will be analogous to those of the similar bodies in the sister kingdoms. Six cities or towns—Dublin, Belfast, Cork, Limerick, Londonderry, and Waterford—will be constituted county boroughs, without much change in administration. In the case of other towns and boroughs, every place which is at present, or may become, an urban sanitary district, will be an urban district under the Bill, having its affairs administered by an Urban District Council, which will be the rating Authority. These Councils will be more independent of the County Councils than the Rural District Councils. But it is needless at present to enter further into the scope of the Bill. Opportunities will occur later on for discussing its provisions in detail. Meantime we shall content ourselves with congratulating the sister island on the prospect of possessing, by the spring of next year, a system of democratic local government such as we now enjoy.

The Promised Sewage Commission.

No Government proposal of recent years has, we take it, excited such widespread satisfaction among sanitarians as has the decision to appoint a Royal Commission to study the various methods for the disposal of town sewage. While it can hardly be said that the problem has yet reached the stage for a perfect solution, the progress that it has made has been such as to warrant the belief that that stage cannot now be far off. As to the importance of the question the consensus of opinion is unanimous. Of all the problems of sanitation which at present exercise the minds of chemists, doctors, and engineers, this problem is probably the one which engages the deepest interest and attention. But beyond that point unanimity stops. Of the three leading methods of treatment—by land, by chemical and mechanical precipitation, and by bacteriological or biological agency—no one has yet succeeded in completely ousting the others. Each system finds its advocates; each can claim to have produced successful results; finality is yet, however, to be attained.

The Need for the Inquiry.

In the present conflict of expert opinion, therefore, it is not surprising that Local Authorities, which are composed of men who are not experts, should be at a loss to determine which way lies salvation. What they want is more light—an exhaustive inquiry into the efficiency and cost of all the various methods, and a careful weighing and comparison of scientific opinion. The insistence of the Local Government Board on some land treatment, in addition to the chemical and other methods that may be employed, in opposition to the views of many eminent experts, has rendered it imperative that we should have an authoritative pronouncement on this all-important question. And therefore it is that the promised Commission will be welcomed by all who desire to see this matter probed to the bottom. As to the composition of the Commission, it is understood that a number of experts in different branches of science relating to the subject, as well as some persons of administrative capacity, have been selected, so that its membership is already practically, if not officially, settled.

The Case of Oswestry.

The experience of Oswestry, which has been described by the Mayor in an interesting letter to the *Standard*, affords a very instructive illustration of the perplexities and difficulties encountered by Local Authorities in dealing with this question. For a number of years the Town Council of that place have been in search of an effectual and economical method of purifying their sewage, and finally they engaged an eminent firm of engineers to report on the matter. But when they found that the scheme recommended, which included a sewage farm and sludge works, was to cost about £20,000, and would probably entail a sixpenny rate, they considered that the expense was prohibitive, and cast about for some cheaper mode. The Council ultimately decided to embark on some experiments on the lines developed by Mr. Dibdin. Mr. Wynne Roberts, the borough engineer, suggested that cinders screened out of the town refuse could be utilised as the filtering media, and that simple earthen embankments would suffice instead of the usual expensive walls. The suggestion was adopted, and the experiments yielded the most satisfactory results, from 90 to 95 per cent. of the impurities being eliminated, leaving a remarkably pure effluent. The Council were so pleased with the results of the experiments that they resolved to construct large works on similar lines. The works are expected to cost about £1500, exclusive of the land, and the annual cost to the ratepayers, after the completion of the works, will be a three-farthing rate, instead of the sixpenny rate that they were at first threatened with.

The Outbreak of Small-pox in Middlesbrough.

The energetic action of the Authorities in dealing with the outbreak of small-pox in Middlesbrough merits the highest commendation, but the ravages of the disease have already been most alarming, and the local tradesmen are suffering considerably from the consequent curtailment of business. The Board Schools are still open, but some of the Voluntary Schools have been closed. Last week the average

daily number of cases notified was about 30, the total number since the beginning of the outbreak being about 500. Almost the whole of the inhabitants of the town have been re-vaccinated, and the Sanitary Authorities have made a most liberal distribution of disinfectants; in one day 20,000 bottles of carbolic acid were given out. The origin of the outbreak is meantime rather obscure. Some reports attribute it to a case of small-pox in a travelling show. Others set it down to the trade with Bilbao, where the malady has been raging for some time, as a considerable number of vessels trade between Spain and the Tees. However this may be, it is satisfactory to learn that the rapid provision of hospital accommodation, in connection with which men have been working day and night, and the other measures taken by the Local Authorities, warrant the expectation that the outbreak will soon be stamped out.

The Plague in India.

The latest news of the plague in Bombay is slightly more reassuring. The number of deaths for the week ending February 18th was 1136, showing a decrease of eighty-four on the numbers for the previous week. As the Earl of Onslow, Under-Secretary for India, stated in the House of Lords last Friday, this is the first time for ten weeks that the weekly telegrams have not shown a progressive increase in the reported plague deaths in Bombay city. The first indication of a decrease is undoubtedly satisfactory; but in other respects, the account of affairs is still most distressing. Two more European nurses have been attacked; and one, a Miss McDougall, died on February 28th. She caught the contagion through bending over the bed of a patient, while seized with a fit of coughing, with the result that some particles of the sputum entered her eye. Then, a most unfortunate fire has destroyed three of the plague hospitals, assigned respectively to European, Hindu, and Parsee patients; the nurses' quarters were also destroyed, and the six English nurses lost all their property. Luckily, the patients were removed in safety; but three of the Hindus died subsequently, from the shock of removal.

Worse than last year.

Altogether the conditions are said to be worse than they were last year. The reported plague deaths in Bombay for the three weeks ending 28th January, 4th February, and 11th February last were 840, 1004, and 1220 respectively. Last year the figures for the corresponding weeks were only 402, 607, and 803. In comparing these figures, however, it must be borne in mind that the exodus produced by the panic last year reduced the population of the city to 450,000, whereas this year the population is estimated to be about 800,000, which is more like its normal condition. The absence of panic this year, indeed, has been the one redeeming feature in connection with the present visitation, and this must have been of very great assistance to the Authorities in the enforcement of the sanitary regulations.

The Measures of Inoculation.

The system of preventive inoculation of Dr. Haffkine has been largely taken advantage of. Lord Onslow states that the Government of India consider that the results of his experiments at Damaun have been so encouraging that hopes are entertained that this prophylactic method may prove to afford a real and efficacious protection against the disease. They recommend that every opportunity should be taken to test its efficacy, and Local Authorities have been directed to procure a supply of serum for the use of persons who desire to have themselves inoculated. Dr. Haffkine himself has been instructed to proceed to Baroda to carry out inoculation there. On this and other matters full information will shortly be accessible to everyone, for a Blue-book dealing with the whole subject is at present in course of being published, and will be ready almost immediately. It is sincerely to be hoped that the heroic efforts of the Government to check the spread of the disease and mitigate the extent of the suffering, and the labours of the devoted band of doctors and nurses, who have carried on the struggle at the risk and sometimes with the sacrifice of their lives, will soon meet with the reward that they deserve.

Public Health Chair for Glasgow University.

The feeling that the time is now ripe for the establishment of a Chair of Public Health in the University of Glasgow, the need for which we emphasised last week, is likely ere long to take some practical shape. The resignation of Professor Simpson affords an opportunity for separating the subjects of medical jurisprudence and public health, which have hitherto been taught together, such as may not occur again for a long time. Sir William Gairdner, whose eminent services to the cause of hygiene have found fitting recognition in his recent knighthood, has taken the matter up with characteristic zeal and earnestness; and alike in University circles and before the public he has been advocating the need for this important chair. In a well-reasoned memorandum which he submitted the other day to the University Court he lays stress on the important place Glasgow has taken during the last thirty years among the cities of the kingdom in the development of sanitation as a department of municipal organisation, so that "from a squalid and unwholesome notoriety as one of the most degraded of cities in this respect, it has emerged into the position of one of the most advanced in dealing with all the manifold problems of prevention."

The Civic Example.

Sir William points out in detail the successive steps that have been taken by the municipality in its progress towards this great ideal, and proceeds to argue that in a city "where all the known machinery for the prevention of disease is now in operation under the superintendence of a Medical Officer of the highest reputation and a staff of Inspectors hitherto never excelled, if indeed equalled, it cannot but have struck many persons as an anomaly that the teaching of this subject has so greatly lagged behind the actual civic example." And he goes on to ask, "Why has the University, which ought to be the centre of light and leading, so that all great questions affecting the community might be expected to be adequately represented in teaching, remained in almost the same state as regards this overwhelmingly great subject as it was forty or fifty years

ago?" We must have a Chair of Public Health, he adds, at all costs, and now is the time to effect this.

The Equipment of the Chair.

These are weighty words, and coming as they do from a man of the eminence of Professor Gairdner, we have no doubt that they will carry great weight with the University Court, with whom the initiative rests. In a wealthy city like Glasgow, the difficulty of providing the necessary funds should not prove overwhelming. For beyond all things, the Chair would have to be liberally endowed and adequately equipped. Not only would there require to be such a salary attached to it as would induce a man of ability and experience to devote his whole time to the subject, but it would be imperative also to have an independent laboratory equal to the highest requirements of the day. Thus only would it be possible to raise the subject of public health in the scheme of University instruction to "the rank required alike by the progress of events and the great extension of scientific knowledge, and adapted to the requirements not only of medical students and candidates for a diploma in public health, but of all, including Sanitary Inspectors and men engaged in local government, who may be expected in future to participate in the desire for systematic and practical teaching in this great department."

A Surveying Bicycle.

Surveyors will be interested to know that a new machine has just been brought out which will be probably most useful to them. Like most startling ideas, the invention has been developed in America. By means of an attachment the exact topographical characteristics of a road may be ascertained with no further exertion on the part of the surveyor than to ride along the road in question. The rider may travel as fast or as slow as he likes, but when he has finished his ride it is stated that the machine will have recorded every gradient or hollow traversed of his route on a long strip of paper which forms part of the attachment in question. The mechanism is claimed to be very simple, and can be attached to any cycle.

Salford Sewage Purification Experiments.

In our issue of last week will be found—on page 199—the report of an interesting paper on this subject, given by the deputy borough surveyor of Salford. At Salford as elsewhere, following on the lines of the Barking filter, biological filters have been in work for several years for the treatment of the effluent from chemical precipitation tanks, with the usual record of success. Indeed, if the figures given are correct, we believe it will be found that the work effected by the Salford biological filters is found to exceed in a very unaccountable measure that done by any other biological filters of which we are aware. The Barking filter was found to produce the most satisfactory results when worked at the rate of one million gallons per acre per day, or 206½ gallons per super yard, but the Salford filters are asserted to have produced good results when worked for twelve months at the rate of 1000 gallons per super yard per day, which is equivalent to 4,840,000 gallons per acre, or nearly five times that which, under the hands of an able chemist, could be done by the Barking filter; and at the present time the Salford filters are being worked at the rate of 700 gallons, or nearly 3½ million gallons per acre per day.

It would be interesting to very many of our readers, we are sure, if Mr. Whyatt would furnish the chemical analyses of the filtrates produced by this remarkable rate of working, for although the results are announced as being "good," we are bound to observe that this qualification is one of very varying degree. Incidentally, it may also be asked why, if the rate of 1000 gallons working was "good," it has been reduced to 700 gallons per super yard? When we mention that the rate of filtration through the sand filters of the London water companies is 540 gallons per square yard per twenty-four hours it will be seen that there is room for grave doubt as to the accuracy of the figures in the Salford experiments. There are circumstances in connection with each kind of filter which require to be taken into consideration, but these have not been overlooked by us. Another notable feature in the Salford experiments is that the filters are, we are told, worked on the "constant" system as distinguished from the ordinary bacteria filter, the success of which is most marked when worked "intermittently." Altogether we are bound to admit that the statistics produced relating to the working of the Salford filters are extremely interesting, and while we hope their correctness may be confirmed, we feel it advisable to reserve judgment until additional particulars and analyses are forthcoming, which we hope will be the case.

Health Lectures.

We have pleasure in drawing attention to a useful and interesting course of lectures to be delivered in the Lecture-room of the National Health Society, 53, Berners-street, on "Public Health Law." The date of the first is the 22nd inst. It deals with the growth of sanitary legislation, and gives information as to the law with regard to infectious diseases. On the 25th inst. the lecturer, Miss A. Ravenhill, will treat of the practical application of the health laws in every-day life, directing her remarks to the management of the house. The third lecture deals with the health of workers in factories and elsewhere; and the fourth will be a practical comment on the machinery for securing healthy conditions in towns and villages. Under the auspices of the same society, Dr. Schofield will deliver a series of six lectures in the Church House, Porchester-terrace, on "Domestic and Personal Hygiene."

Leyburn.—The Rural District Council has instructed Mr. William Spinks, C.E., of Leeds, to prepare a scheme of water supply for the district of Finghall.

Tadcaster.—The Rural District Council has approved the scheme of sewerage and sewage disposal for Stanks and New Manston, prepared by Mr. William Spinks, C.E., of Leeds, and has forwarded the plans to the Parish Council for its consideration.

NOTES ON PRACTICAL SANITARY SCIENCE.

By WILLIAM H. MAXWELL.

Assistant Engineer and Surveyor, Leyton Urban District Council, Author of "Drainage Work and Sanitary Fittings," "Ventilation, Heating, and Lighting," &c., Certificates of the Association of Municipal and County Engineers, and Sanitary Institute.

No. 51.—REFUSE DESTRUCTORS.

(Continued from page 195.)

The Meldrum Furnace.

The Meldrum patent "Simplex" destructor is a modern apparatus manufactured by Messrs. Meldrum Bros., of Manchester. In this furnace, it is claimed, ordinary town's refuse will give a sufficiently high temperature to utterly decompose all noxious material, nothing but harmless and inoffensive gases passing up the chimney, the solid residue consisting entirely of hard clinker with a little ash. When it is desired to utilise all the available heat for steam-raising a special internally fired-steam generator is employed.

Ordinarily, the furnaces are fed by hand, but hopper feeding may be arranged if required. A forced draught is used in connection with the furnace, but no cremator is considered necessary, owing to the high temperature of the cells.

From the accompanying figures (17 and 18) it will be observed that four grates are placed side by side and separated only by dead plates, the ashpit, however, being divided in four parts, each separately fed with a supply of air under pressure, preferably by steam air blast. The destructor, therefore, is practically a single cell, fed and cleaned in four places at regular intervals, so that an approximately constant temperature may be anticipated.

The escaping gases either pass away from the back of each fire-grate into a common flue leading to boilers or the chimney, or are conveyed sideways over the various grates, and thence over a common fire-bridge towards the boilers or chimney. After passing the fire-bridge it will be seen there are five rows of baffle pillars arranged to divide and break up the current of hot gases; the pillars remain constantly at a bright red or white heat, and take the place, it is claimed, of the cremator furnace commonly used in the older destructor installations. A bye-pass is, of course, provided in order that the furnaces may be used without the boilers. The patentees recommend the four grates be laid down as shown in the accompanying illustrations, but fewer or more may be provided to suit circumstances. One or more of the grates may be disused without interfering with the working of the remaining portion of the destructor.

The main object of the "Meldrum" furnace, which may also be applied to every description of boiler and are now to be found fitted in almost all parts of the world, is to economise the cost of evaporation by the use of the commonest and poorest kinds of fuel, as coal or coke dust, ashpit refuse, &c.

The ashpits are closed by a cast iron plate, fitting air-tight, and provided with an air-tight door for removing the fine ash. Two patent steam jet blowers are provided for each furnace, lying within the ashpit, and fixed to the ashpit front. Steam is supplied to the two blowers from one steam pipe, the air blast being regulated at will by a steam cock or valve. The blowers are the simplest form of jet apparatus made, and use no more steam than necessary to preserve the bars, and, it is said, less than that evaporated from the water bath adopted in some systems for keeping the bars cool. The blowers are constructed to give any required pressure of blast, to 6in. water column and upwards for special circumstances, but, as a rule, no more than 1in. to 1½in. is required. Some of the advantages claimed for this system of forced draught are:—Any kind of fuel, however inferior, can be burnt; no tall chimney is required; evaporative power increased; clinkers are prevented from adhering to the fire-bars; the fire-bars are preserved.

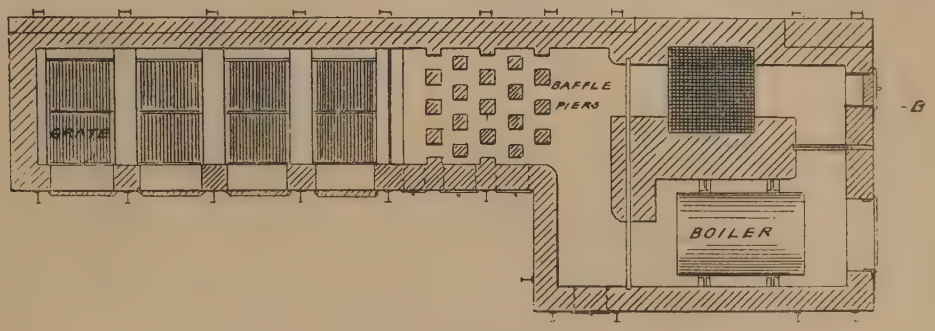

Fig. 17.—"Meldrum" Destructor. Plan.

The patent fire-bars (see Fig. 19) are provided with a special locking arrangement to prevent any bars being accidentally lifted when cleaning; this avoids burning, and in consequence the bars, with judicious use, will last for many years. The bars are spaced under ⅛in. apart, so that nothing of value can fall through. The saving of fuel, in the case of ordinary boiler furnaces, from this source alone, is said to more than cover the cost of steam for working the blowers.

At Basingstoke the sewage of the town is being pumped by means of power derived from the burning of town refuse in Meldrum's forced draught furnaces, and on November 17th, 1893, nine hours' pumping took 23 cwt. 2 qr. of refuse to keep up 45 lb. pressure of steam, which lifted 274,000 gallons of sewage 100ft. high.

In regard to the question of the number of

"Meldrum" cells required proportionately to any given population, if we take the annual production of house refuse per 1000 inhabitants at 200 tons, then a single "cell," that is a grate 5ft. by 18ft., having four ashpits, and burning at an assumed average rate of 40 lb. per square foot per hour, would consume (90 square feet × 40 lb. × 24 hours) about 38 tons per day of 24 hours, or per year of 300 days = say, 10,000 tons. Consequently, if this rate of consumption be uniform and constant throughout the year, such a cell or destructor should suffice for $\frac{10,000}{200} = 50,000$ people.

The heat derived in indicated horse-power per cell would, theoretically—assuming a maximum duty of 2 lb. of water evaporated per lb. of refuse consumed—be equal to $\frac{90 \text{ sq. ft.} \times 40 \text{ lb.} \times 2}{20} =$ 360-horse power continuously per cell at 20 lb. steam per 1-horse power per hour.

A height of chimney shaft of 40ft. is said to be ample for the requirements of the "Meldrum" furnace; and the temperature in the cell if fitted with regenerator may be taken as averaging about 2000 deg. Fah.

A four-cell destructor has been working at Rochdale for some three years, and cells are being fitted at Hyde, near Manchester; also four of the cells, or rather one four-ashpit destructor is now being erected, attached to two Lancashire boilers at the sewage-pumping station, Hereford.

In a letter appearing in the *Contract Journal*, of March 17th, 1897, in connection with the recent Cardiff Report on the Disposal of Towns' Refuse, it is observed that Mr. Harpur, Borough Engineer, Cardiff, concludes that town refuse will not make steam beyond a pressure of 70 lb. per square inch; but, it is further stated, Meldrum Brothers are prepared to guarantee to evaporate steam at 180 lb. or 200 lb. pressure, the fuel being unscreened town's refuse.

The actual pressure maintained at Rochdale is given at 110 lb. per square inch. Electrical engineers usually desire a pressure of about 150 lb. to 160 lb., and, it is claimed, a destructor on the "Meldrum" principle would maintain this pressure without difficulty.

In regard to the question of steam, the following evaporative tests will be of interest:—

Evaporative Tests made on a Lancashire boiler, 28ft. by 7ft., flues 2ft. 9in. diameter, fitted with "Meldrum Furnaces" at the *Salford Sewage Works*, Mode Wheel. Fuel used, unscreened ashpit refuse.

Date of test	Feb. 19 and 20, 1895.
Duration of test	14 h. 10 min.
Weight of unscreened ashpit refuse burned ...	18,704 lb.
Average steam pressure ...	50·5 lb.
Average temperature of feed-water	42·9 deg. Fah.
Water evaporated during test	36,000 lb.
Refuse burnt per hour... ...	1320 lb.
Water evaporated per hour...	2540 lb.
Water evaporated in lbs. per lb. of refuse, actual conditions	1·9 lb.
Water evaporated per lb. of refuse, from and at 212 deg. Fah.	2·28 lb.

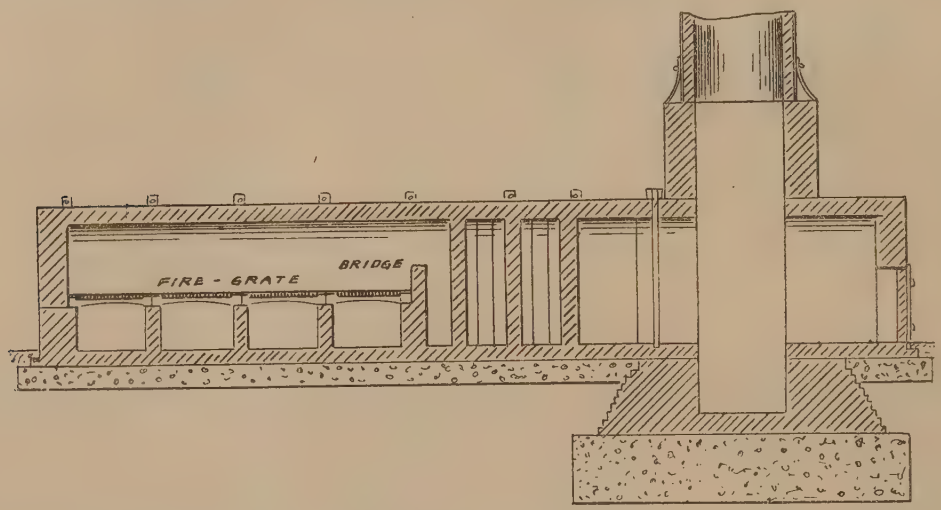

Fig. 18.—"Meldrum" Destructor. Section.

Evaporative Test of unscreened ashpit refuse burned in Meldrum furnaces, fitted in front of two Lancashire boilers 30ft. by 8ft., with two flues of 3ft. diameter, at the *Rochdale Sanitary Works*, March 1st, 1895.

Duration of test	6 hours.
Average steam pressure ...	113 lb.
Average temperature of feed-water	53 deg. Fah.
Total water evaporated ...	4207 gallons.
Total refuse burned	11·4 tons.
Total residue (clinker)... ...	4·15 tons.
Temperature in combustion chamber at 4 o'clock, tested with Siemens' Pyrometer	1988 deg. Fah.
Ditto, ditto, at 4·30 o'clock after clinkering and feeding	1290 deg. Fah.
Water evaporated per boiler per hour	350 gallons.
Refuse burned per boiler per hour	2123 lb.
Water evaporated per lb. of refuse (actual) ...	1·64 lb.

Water evaporated per lb. of refuse, from and at 212 deg. Fah.	1·97 lb.
Percentage of clinker to refuse	36 per cent.

Blowers supplied with steam at 55 lb. pressure from separate range of boilers.

Mr. Stevenson Macadam, Ph.D., F.I.C., writing in the *Journal* of the Society of Chemical Industry[132] upon refuse destructors, observes that his inspection of this destructor at full work satisfied him "that an excellent temperature could be got up and maintained in the various grates when all the doors were closed, but the mode of charging the respective grates by hand feeding, with the doors open, led to the entrance of much air into the combination, which must necessarily have a cooling influence on the whole, and lessen the efficiency of this destructor for consuming the smelling gases evolved from the foul garbage, especially when the newly-charged grate is near the chimney end of the combination." It should, however, be noted that after passing the fire-bridge the gases come in contact with the baffle pillars above described which if maintained at a "bright red or white heat" must have an important effect towards ensuring the perfect combustion of all offensive vapours.

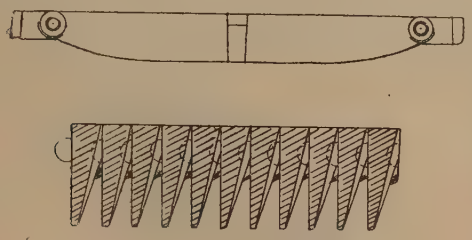

Fig. 19.—The "Meldrum" Firebars.

At Rochdale is a destructor of this class, designed by Mr. Brookman, with Meldrum's grates and steam jet blowers. The cost for labour is put down at 10d. per ton. Three men can dispose of 10 tons of refuse in ten hours in each of the two cells; this, with wages at 25s. per week per man gives 7½d. per ton for labour at the furnaces—adding to this a proportion of the expenses of supervision, &c., making the cost 10d.

THE SANITATION OF DOMESTIC BUILDINGS.

By Frank Latham, C.E., M. San. Inst., &c., Assistant Surveyor, Borough of Margate.

CHAPTER V.

INSPECTION CHAMBERS.

Inspection chambers or manholes are shafts constructed in the course of drains, and conducting thereto for the purposes of supervision and cleansing, so that in the event of obstruction in, or accident, such matter may receive immediate and effective attention. Inspection chambers are, as a general rule, placed at angles in drains, or where junctions occur and are fitted with sealing covers, thus preventing the escape of air or gas, and although they may not appear imperatively necessary in cases of small and simple systems of house drainage, still it is most desirable that access to all drains should be thus readily obtainable. Inspection chambers should in every instance be provided at both ends of the length of drains which pass under houses or in immediate proximity to a water supply, and in situation of similar importance

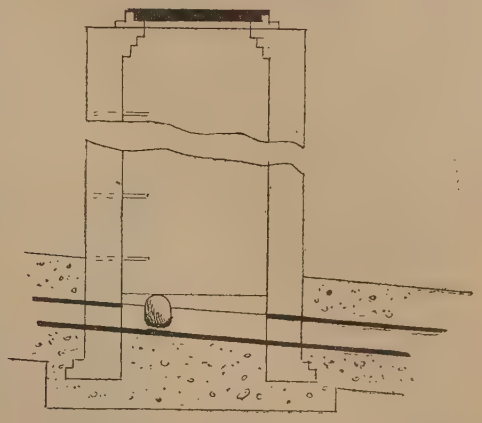

Fig. 41.

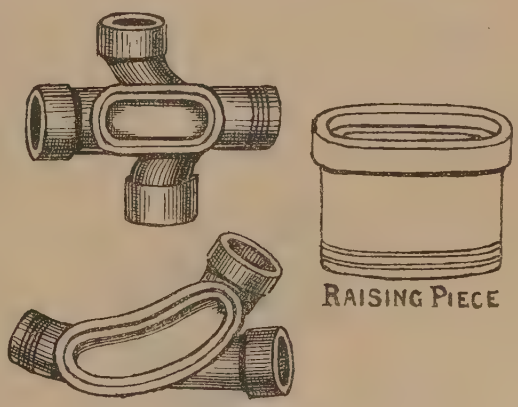
in order that occasional examination of such drains may be made and their soundness ascertained. (Fig. 41.) In the absence of means of easy access it would be impossible to efficiently and satisfactorily conduct such examinations without incurring much expense and delay, by excavating the ground and opening down to the drains for the purpose. Inspection chambers ought also to be placed at every point where the drain deviates in its course to any great extent, from the direct line, and drains should be so planned that as many branch drains as possible converge to and connect up by means of open bends within the chamber. When, however, it would require to extend branch drains to any considerable length to form this connection, it is better that inspection pipes should be employed in such cases. These inspection pipes are ordinary pipes with an opening at the top; they are particularly useful in providing means for examination of branch drains, and should be regularly used for that purpose. (Figs. 42 and 43 and raising piece.)



Figs. 42 and 43

In the cases of long lengths of house drains, it is requisite that inspection chambers be provided at

[132] March 31st, 1893.

frequent intervals in their courses to afford proper supervision and control. It is advisable, moreover, to place an inspection chamber in connection with intercepting traps upon the house side of the trap,

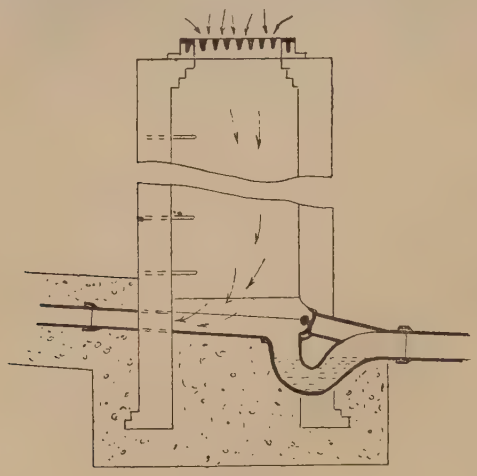


Fig. 44

so that in the event of its becoming choked as sometimes happens, ready access and relief can be at once obtained. (Fig. 44.)

These chambers should be constructed square in plan, with walls of good hard stock bricks, or other non-absorbent materials 9in. in thickness, on good footings, and in cement mortar throughout, and

Fig. 45.

with proper struck joints. When deep, step irons should be built in on one side of the wall to form a ladder. (Fig. 45.) The floor of the shaft should be of 9in. of good Portland cement concrete properly rammed to the levels required for the channels. The main invert channel should be laid with correct levels, and embedded

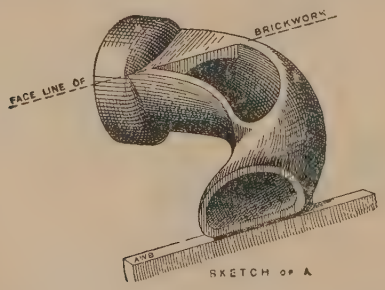

Fig. 46.

in fine concrete which should be extended to the sides of the chamber, with a good fall to the central main drain, and well benched up in cement. The sides of the chamber should be rendered in cement to the height of a few feet above floor level, and at the top of the chamber a square inspection cover frame should be fixed, the brickwork being corbelled over if necessary. The main invert channels used in these chambers should be of the same size, and laid at the same gradient and level as the drain. The open channel bends should be constructed so as to prevent the sewage splashing over the channel and depositing

Fig. 47.

on the sides, or on the benchings and corners, thereby rendering the inspection chamber filthy and unsanitary. To obviate this it is necessary to use channels specially manufactured for that purpose, the old system of employing ordinary semi-circular channels not being continued.

Jones and Sykes' patent channel bends (Fig. 46) have been designed to deliver the sewage into the main channel in a cleanly and efficient

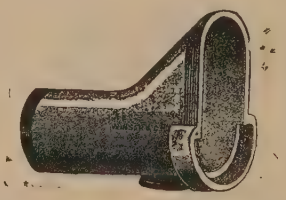

Fig. 48.

manner, without creating any undue disturbance in its regular flow. Winser's channel pipes (Fig. 47) are constructed with a similar object, and are very satisfactory in operation. In these the outer side is carried higher than the inner and curved inward, thus counteracting the tendency of the sewage to overflow on that side and preventing its so doing. This firm also manufacture a special drain chute for inspection chambers. (Fig. 48.) This is a pipe

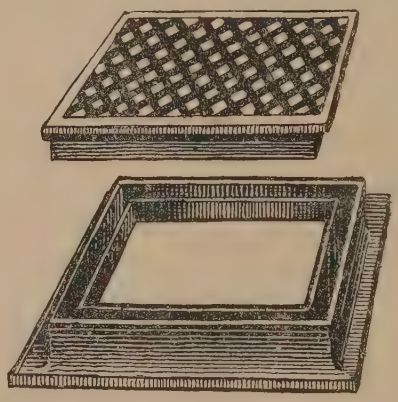

Fig. 49.

the upper side of which is opened to form a hood at the socket end, and is useful as the first outlet pipe from open channels. It affords easy access for the cleansing rods.

Inspection chambers should be covered with proper iron sealing covers, such as Adams'

Crappers', or Jones' (Fig. 49), and have a flanged edge fitting into a groove in the frame. This groove should be run with Russian tallow in order to render the fitting air-tight, and as drain air is apt to accumulate in inspection chambers, it is advisable to place an air inlet (such as the mica valve ventilator) at the top of the chamber in order to maintain a current of air through it. Double sealing covers are to be recommended, such as Jones' patent. (Fig. 50.) When the drain is situate at a short distance from the surface of the ground, the use of inspection pipes and eyes may be adopted in lieu of inspection chambers. These pipes and

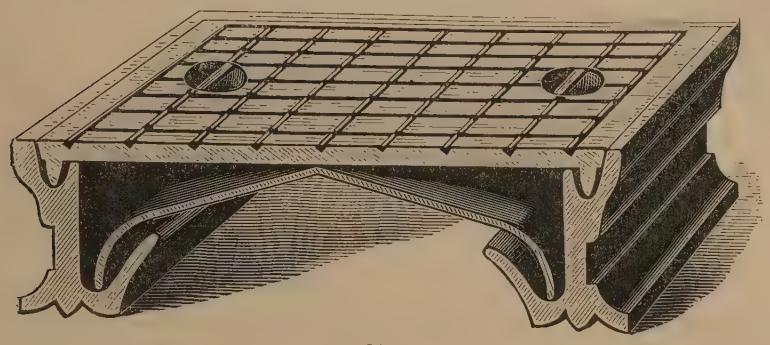

Fig. 50.

eyes are manufactured in a variety of shapes, but in the best forms the sides of the pipes are brought up higher than usual, and constructed with rectangular openings above the ordinary water line. These openings should be fitted with locking covers to prevent any internal pressure from bursting them open. Circular inspection eyes at the ends of drains and other places for cleansing and flushing purposes should be provided with screw stoppers and blocks, and by the use of Russian tallow between the joints they are rendered effectually air-tight.

THE SUCCESS OF VACCINATION AND OTHER PREVENTIVE MEASURES IN SMALL-POX.

By MEREDITH YOUNG, M.D., Mast. Surg., D.P.H., Medical Officer of Health and Med. Supt. Crewe Corporation Hospitals.

THE figures quoted in this article are based upon my own observations on 150 cases of small-pox when Medical Superintendent of the Brighouse and District Joint Hospital (Yorks). These cases, classified according to their state as regards vaccination were as follows:—

36 cases never vaccinated;
101 „ once vaccinated;
9 „ re-vaccinated; and
4 „ doubtful.

I propose to consider with reference to each class (1) the total mortality and the mortality at various age periods; (2) the nature of attack in each class as a whole and at various age periods.

I.—In the unvaccinated class there were 36 cases and 11 deaths recorded; the mortality was thus 30·55 per cent. of the cases. In the once-vaccinated class there were 101 cases with 5 deaths, the case-mortality thus being 4·95 per cent. In the re-vaccinated class there were 9 cases with no deaths; and in the doubtful class 4 cases, with two deaths. Thus the mortality in the unvaccinated class was slightly more than six times as great as in the once-vaccinated class.

Taking now the mortality at different age periods in the never-vaccinated and the once-vaccinated classes, and excluding three cases under three months of age and never vaccinated for the sake of absolute fairness, we find, as the following tables will show, (1) that the cases in once-vaccinated persons under 20 years of age were very few; (2) that no death occurred under the age of 30 years; (3) that in the never-vaccinated class the largest number of attacks were at ages under 10 years, and that 7 out of a total of 9 deaths occurred within the first ten years of life; (4) that the case-mortality in the once vaccinated never reached 16 per cent. at any age, whilst in the re-vaccinated the *lowest* case-mortality was just over 16 per cent. Had the rate of mortality been the same in the once vaccinated as in the unvaccinated, the deaths amongst vaccinated persons would have been 27 instead of 5.

It must be borne in mind, too, that the vaccinated class includes a number of cases—nearly one-sixth—in which the vaccination marks were decidedly poor.

Once-vaccinated cases.

Ages in years.	Total attacks.	Total deaths.
0— 1	2	0
1— 5	2	0
5—10	2	0
10—15	3	0
15—20	6	0
20—30	31	0
30—40	36	2 (5·55)
Over 40	19	3 (15·7)
All ages	101	5 (4·95)

Unvaccinated cases.

Ages in years.	Total attacks.	Total deaths.
0— 1	4	2 (50·0)
1— 5	12	4 (33·3)
5—10	6	1 (16·6)
10—15	5	0
15—20	2	0
20—30	2	2 (100·0)
30—40	1	0
Over 40	1	0
All ages	33	9 (27·27)

The figures in brackets give the case-mortality per cent., but of course the figures are only small for such calculations.

II.—Turning now to the nature of attack in the several classes as a whole, and in the same classes at different age periods. (1) Of the 33 unvaccinated cases 13 were discrete and 20 were confluent attacks. (2) Of the 101 once-vaccinated cases, 85 were discrete, 13 were confluent, and 3 were hæmorrhagic attacks. (3) Of the 9 re-vaccinated cases all were the mildest possible discrete attacks, the worst case having but eight spots. (4) Of the

4 "doubtful" cases 1 was discrete, 2 confluent, and 1 hæmorrhagic. Thus, taking the proportions of discrete and confluent cases to total cases in each class, we find that in the once-vaccinated the discrete cases were in double ratio to such mild cases in the never-vaccinated, and that the confluent attacks in the never-vaccinated class were nearly five times greater in proportion than among the vaccinated.

The nature of attack in the once-vaccinated and never-vaccinated classes at different age periods is shown in the following tables :—

Once Vaccinated.

Age in years.	Character of attack. Discrete.	Confluent.	Hæmorrhagic.	Deaths.
0— 1 ...	2	0	0	0
1— 5 ...	2	0	0	0
5—10 ...	2	0	0	0
10—15 ...	3	0	0	0
15—20 ...	5	1	0	0
20—30 ...	29	2	0	0
30—40 ...	31	5	0	2
Over 40 ...	11	5	3	3
All ages	85	13	3	5

Unvaccinated.

Age in years.	Character of attack. Discrete.	Confluent.	Deaths.
0— 1 ...	2	2	2
1— 5 ...	5	7	4
5—10 ...	3	3	1
10—15 ...	2	3	0
15—20 ..	1	1	0
20—30 ...	0	2	2
30—40 ...	0	1	0
Over 40 ...	0	1	0
All ages ...	13	20	9

From these tables it will be apparent (1) that the more severe cases did not appear in the vaccinated class until a comparatively late age, and that as age advanced the number of severe cases increased. The occurrence of three hæmorrhagic cases at ages over 40 is to be noticed ; the exact ages of these patients were 43, 45, and 59 years. (2) That in the unvaccinated class the greater number of severe attacks were at early ages.

The facts as to the re-vaccinated cases are set out in the following table :—

Age in years.	Sex.	Character of Primary Scars.	Character of Attack.
35	F	3 medium sized, foveated.	4 spots.
37	F	1 ditto, ditto	8 spots.
38	M	1 ditto, slightly foveated.	6 spots.
22	M	2 ditto, ditto.	7 spots.
29	F	Not observed.	Few abortive spots.
29	F	Ditto	Ditto.
22	M	4 large sized, foveated.	4 spots.
17	F	Not observed.	5 spots.
18	M	3 medium sized, foveated.	5 spots.

In all of these cases the re-vaccination was performed after the appearance of small-pox in the house or in the immediate neighbourhood ; that is after risk of infection had been incurred. Needless to say, all these cases recovered, none of them being confined to bed at any stage of the disease.

As a further means of showing the influence of vaccination upon the nature of attack, we may consider the number of abortive attacks in each class, the term abortive being here applied to those attacks (which were always discrete) where the eruption did not attain the pustular stage at least. In the majority of these abortive attacks the eruption simply became papular, and without any vesiculation taking place the papules died away.

Abortive Attacks (150 *cases considered.*)

Under 10 years of age.	Unvaccinated (See Note A) ...	4
	Once vaccinated	4
	Re-vaccinated	0
Over 10 years of age.	Unvaccinated	0
	Once vaccinated (See Note B)	24
	Re-vaccinated	9

Note A.—In three of these cases one was vaccinated on the 5th day of incubation, but the vaccination marks, beyond causing some slight irritation for a few days, did not apparently take. In another of these cases the vaccination was performed on the 9th day of incubation, but showed no external sign of having taken. In a third case vaccination was performed on the 8th day of incubation ; the marks became papular and then died away.

In all three of these cases it is conceivable that the vaccination had some effect in modifying the disease, although it showed no special local evidence of having taken.

Note B.—In one of these cases re-vaccination was performed on the 6th day of incubation, but gave no external sign of having been successful. The figures referring to attacks at ages over ten years of age are in favour of vaccination, and strongly in favour of re-vaccination, as agents modifying the severity of attack.

(*To be continued.*)

TUBERCULOSIS: A MENACE TO PUBLIC HEALTH.*

By Dr. WILLIAM BROWN, F.R.C.S.E., Medical Officer of Health, Carlisle.

IN an annual report on the health of Carlisle of a few years ago under the subject of tuberculous meat, I made the following observation :—"That there is real risk in eating the flesh of tubercular animals is unquestionable, but it is infinitesimal compared with the risks of partaking of milk derived from tubercular cows. On several occasions during my visits to the Public Slaughter-house I have seen the udders of cows affected with marked tubercular disease. In such cases the tubercular infection passes directly into the milk, and as this article of food is generally taken in the uncooked state, the danger of infection becomes very great. Until we in this country adopt the system of veterinary inspection of animals, such as exists in Denmark, milk infection will constitute the real danger of tuberculosis being transmitted from animals to human beings."

Further experience, gained by a systematic examination of the various parts of tubercular carcases at the Carlisle Public Slaughter-house, has afforded additional evidence of the truth of the opinion expressed in the foregoing statement as to

* Annual Report, 1897.

the risks of transmission of bovine tuberculosis to man from the ingestion of milk derived from udders affected with tubercular disease.

The life history of the specific micro-organism which during recent years has been found to be the cause of human and animal tuberculosis is now as thoroughly worked out, and perhaps even better than, that of the germ producing the well-known disease anthrax, so fatal to man and animals.

A tiny drop of anthrax blood taken from an animal dead of anthrax, when injected under the skin of an animal of the rodent class like the guinea pig, is followed almost invariably by the death of the animal in the course of twenty-four to forty-eight hours. A guinea pig treated in a similar manner with the tubercular virus dies almost equally surely, though the deadly process is slower, owing to the invading organism in the case of tubercle taking a longer time to accomplish its mortal effect.

The grave question of the possibility of an organism so destructive to human life as the tubercle microbe being present in milk obtained from a tubercular udder of the cow is no chimerical notion, but one which has received a positive and final answer by microscopical demonstration, and simple experimentation, of a harmless kind, upon healthy animals susceptible to tuberculosis.

The tubercular conditions met with in the carcases of bovine cattle at the Carlisle Public Slaughter-house are as follows, arranged irrespective of their order of frequency:—Tuberculosis of the lungs, and their covering the pleural membrane (consumption); the pericardium or heart bag; the bowels and their containing sac the peritoneum; the liver, spleen (melt), and pancreas (sweetbread); the kidneys, bladder, and uterus (womb); the brain and its membranes; the eye; the lymphatic glands of the body; the bones; the udder or milk gland. When we consider the tubercular conditions present in the human subject, we find that they are precisely the same in localisation or parts affected as come under observation in bovine tuberculosis, and every medical man engaged in general practice in Carlisle is confronted with most of the foregoing conditions among his patients in the course of a single year. In England lung tuberculosis or consumption is remarkably common, and tuberculosis of the brain and its membranes, an almost uniformly fatal disease, is of frequent occurrence. Tuberculosis of the lymphatic glands, the kidneys, bladder, bones, and joints form a large portion of the cases which present themselves for treatment at the Cumberland Infirmary and the Carlisle Public Dispensary.

The fatality from the disease in this country is deplorable. A micro-parasitic disease, like those of the zymotic class, it has a mortality in many English towns enormously greater than that from all the so-called zymotic diseases put together. In Carlisle the deaths from tuberculosis for the past three years have been considerably more than double the deaths from the principal zymotic diseases, including scarlet fever, measles, diphtheria, small-pox, whooping-cough, typhus fever, typhoid fever, continued fever, and diarrhœa.

The principal tubercular diseases, including lung tuberculosis (consumption), tuberculosis of the brain and its membranes, and tabes mesenterica (tuberculosis of the abdominal lymphatic glands, &c.), constitute 10·2 per cent. of the total number of deaths from all causes in Carlisle during the past ten years. Other English towns have a similar and even worse experience. Tabes mesenterica, or tuberculosis of the bowels and the lympathic glands interspersed between their coils, is a common cause of death and a still more common disease in Carlisle. It is a highly significant fact that these very two abdominal structures are the ones which first become tubercular when a guinea pig or rabbit is fed upon milk containing small pieces of crushed tubercle taken from a bovine source.

Perhaps there is no laboratory experiment upon animals so impressive from its overwhelming importance than the artificial production of tuberculosis in the abdominal lymphatic glands of a guinea pig or rabbit by feeding it upon bovine tubercle, or upon milk obtained in the ordinary way from the tubercular udder of a living cow. The death of the animal experimented upon usually takes place in from about six to eight weeks from the onset of infection, corresponding pretty much in point of time with the duration of some of the more rapid forms of human tuberculosis, such as acute tuberculosis of the brain and its membranes, and acute tuberculosis of the lung (galloping consumption). A *post-mortem* examination shows that though the coats of the bowels may or may not be visibly affected, the numerous lymphatic glands connected with the conveyance of the products of digestion from the bowels into the blood are, relatively to the size of the animal, enormously swollen from tubercular growth, in the substance of which the deadly tubercle micro-organism can be easily seen with the microscope, and its fatal specific properties tested upon various animals. Another point worthy of note with regard to the disease tabes mesenterica is the fact that it is the most common in young people under twelve years of age, or in other words, among those of the population who are the chief consumers of cows' milk.

Finally, medical science has fully established the fact that human tuberculosis and bovine tuberculosis are one and the same disease, produced by the same germ, and both easily transmitted to healthy animals, such as guinea pigs, rabbits, kittens, and young calves, by the ingestion of milk containing the specific tubercle microbe.

I am induced to bring this subject before the Health Committee at the present time owing to the increased number of tubercular milk glands which have come under observation at the Carlisle public slaughter-house during the past year. Thus, of the thirty cow carcases condemned for general tuberculosis as unfit for human food at the slaughter-house, one in every five had marked tubercular disease of the udder, some of which were in the stage of suppuration with foul smelling matter in their interior. A microscopic examination of portions of the udders subjected to this kind of investigation showed the tubercle germ in abundance.

In a few of the more advanced cases of tubercular udder disease, the milk ducts or channels for the conveyance of the milk secretion to the teats were very much dilated, and partially filled with soft tubercular growth projecting into their interior. A more favourable condition for the production of milk infection could hardly be conceived. I believe I am correct in stating that some of the cows with the tubercular milk glands had been milked until within a short period of their removal to the

slaughter-house. Moreover, the present time is a favourable one for taking action, as the public are now sufficiently educated on the subject of tuberculosis to appreciate the dangers that all classes of the community incur in consuming milk without any guarantee as to its being free from tubercular infection.

I beg to submit the following proposals :—(1) That all dairy cattle from which milk is derived for distribution in the Carlisle urban sanitary district be subjected to regular veterinary inspection ; (2) that a more rigid enforcement of the city bye-laws as to the cubic space of the Carlisle cowsheds be carried out ; (3) that, as an auxiliary measure, the Carlisle Urban District Council extend the provisions of the Infectious Diseases Notification Act to pulmonary phthisis, tubercular meningitis, and tabes mesenterica.

Tubercular disease of the udder in the living animal is, as a rule, easy of detection, and in a case of doubt the milk could be subjected to a microscopical examination with or without the administration of a dose of tuberculin to the animal to dislodge the germ from the milk gland. The general use of tuberculin for the detection of tuberculosis in milch cows is perhaps too advanced a measure to recommend in Carlisle at the present time, though it is systematically carried out in New York City and some parts of the Continent.

A liberal allowance of air space in cowsheds is important. Rearers of dairy cattle are well aware of the infectious nature of bovine tuberculosis and of its spread being very much favoured by overcrowding of animals in confined sheds. Reasoning by analogy from what is known of human tuberculosis we may fairly conclude that the spread of bovine tuberculosis is due apart from milk infection during the calf stage of existence to the presence of the specific microbe in the discharges from the lungs, bowels, bladder, and vagina of the affected animal. Hence the importance of adequate air space, free ventilation, and cleanliness.

Notification of the three principal tubercular diseases would lead to an inquiry as to the source of infection, and thereby put the Sanitary Authority in a position to take measures to limit the spread of the disease. In Berlin the disinfection of premises vacated by consumptive patients has been required by law for at least seven years, and a similar law has been enforced in New York City for four years.

THE PREVENTION OF DISEASE.

THE fifth of the series of Glasgow University Free Lectures was given on the 14th ult., in the Practice of Medicine Lecture-room, by Professor Sir W. T. Gairdner, his subject being "The Prevention of Disease." There was a large attendance.

Professor GAIRDNER said that when he was appointed to a Chair of the University in 1862, Scotland was very backward in all matters connected with public health as compared with England. The science of the prevention of disease was practically a thing of yesterday, and he instanced the disease of scurvy as one which people, including medical men, had been slow to learn anything of. The benefits of lemon juice as a preventive of scurvy were found out by sailors two centuries ago, but still the knowledge had not been acted upon. It was not till the close of last century that the lessons learnt regarding scurvy were brought home and acted upon in the practical manner that they knew of to-day. A great deal had been done by Lord Shaftesbury and other earnest men to spread a knowledge of the importance of the prevention of disease, and much stress was laid on the necessity for cleanliness everywhere. But the invention of the mode of expressing the death-rate of the towns and villages in the country by the late Dr. Farr, of London, was a service that might be called absolutely inestimable in the prevention of disease. Such calculations enabled reformers to see where the greatest number of deaths per 1000 of the population took place, and an investigation into the causes which led to the deaths was the result. It was seen that the death-rate was higher in proportion as the population was more aggregated than where humanity was more scantily spread. Sanitary reform was begun, and the results had been shown in a greatly decreased death-rate. In Glasgow alone since the passing of the Health Improvement Act in 1866 a saving of 10,000 lives in a year had been effected. After speaking of the tendency of the rural population to crowd into the towns, and, in a large majority of cases, to squat down in most unhealthy surroundings, he spoke of the large number of uninhabitable houses which existed in the city, in spite of the power of the Authorities, and went on to say that the Authorities must stick at nothing to do away with the sort of houses in which people could live under any conditions, and so bring about a purer atmosphere than was possible in many parts of Glasgow at present. Glasgow should be placed in such a position that it would be impossible for any person to own a house of that kind. The lecturer concluded by making an appeal for the establishment of a Chair in the University for the teaching of Public Health.

THE SANITAS COMPANY, LIMITED.

THE twenty-first annual general meeting of this company was held at the works, Bethnal Green, recently, under the presidency of the managing director, Mr. T. Kingzett, F.I.C., F.C.S., who congratulated the shareholders on the continued prosperity of the business. Attention was directed to a new preparation entitled "Sanitas Embrocation," which has been recently placed on the market, and to the purchase of the business of the American and Continental Sanitas Company, Limited, as a going concern. In consequence of this purchase the capital of the Sanitas Company, Limited, has been considerably increased during the past year, but the profits of the trading in 1897 were such as to allow of the usual dividend of $13\frac{3}{4}$ per cent. for the year, after making adequate provision for all charges, including depreciation of patents and goodwill account. The reserve fund of the company now amounts to upwards of 20 per cent. of its paid-up capital, and is invested in high-class securities. The main business of the company is that of the manufacture of disinfectants and sanitary preparations and appliances generally.

THE CONTAMINATION OF PUBLIC WATER SUPPLIES.

By FRANCIS SUTTON, Norfolk County Analyst.

REPORTS have been circulated in the newspapers as to sources of possible contamination to the water supply of this city (Norwich) at Drayton and other places along the course of the river from which the Norwich supply is taken. I am of opinion that facts as to the pollution of any public supply should be made known as widely as possible with a view to their prompt removal, but at the same time I think the public should know how these difficulties are successfully dealt with by properly managed water companies, so that practically no harm results.

The deplorable instances of Maidstone and Lynn are typical cases of gross neglect and carelessness with regard to the only thing which could have saved them from danger and death. In my position as a public analyst, I necessarily see and hear more of the anxiety, and even terror, of many people whose fears lead them to adopt measures involving far greater dangers than those they try to escape. An amusing instance occurred a short time ago in which a lady, having seen a statement in some paper that the drainage of a slaughter-house or some piggeries found its way into a watercourse connected with the river Wensum, made up her mind to give up drinking the city supply, and told me she had done so. I asked her what water she intended to drink. Oh! said she, there is a well on my premises which has been shut up for some time because it was said not to be good, but it looks quite clear, and I shall use that. I strongly dissuaded her from such a course, but the well water was analysed, with the discovery that it was of the most filthy description, and contained soakage from places infinitely worse than either slaughter-houses or piggeries, bad as they are. Some nervous people will insist upon filtering the water through a domestic filter, which they have been assured will render almost any water safe. Unless domestic filters are properly constructed and can be efficiently cleansed at very short intervals, they are a positive source of danger, besides which that kind of filtration renders the water stale and unpalatable.

I say with confidence that it is not necessary nor advisable to re-filter the water supplied by the Norwich company if taken direct from their mains. If collected in a cistern open to dust and other kinds of pollution the case may be altogether different. Any water supply derived from an open stream or broad surrounded by cultivated land, pasture, and here and there human dwellings or farm premises, must inevitably suffer more or less from contamination. The Thames in its long course receives an incalculable amount of noxious material, yet when its water is properly dealt with by the various London companies these evils are practically eliminated and destroyed. So far as I am aware, in spite of the inefficient way in which some of the water companies have at times dealt with it, and in spite of the enormous amount of pollution it has received at various points along its course, this London water has never been the cause of outbreaks of enteric fever or other diseases of the zymotic class, although the river itself at various points must have been heavily charged with disease germs and spores which originate such maladies.

What, then, is the protection? The organisms which propagate disease are infinitely small—so small that only the very highest powers of the best microscope can detect them, and their number and power of multiplication under certain circumstances is enormous; yet they have enemies arrayed against them vastly more numerous and powerful than themselves; and fortunately for us this war between microbes of one class and those of another is always going on.

Moreover, sunlight, ordinary daylight, and fresh air are deadly foes to those germs whose baleful influence we fear, but the greatest protection against them is slow, careful filtration through sand, copying by an artificial method the natural one of earth filtration, which gives protection to the waters of deep wells and springs. Of late years the action of these artificial filter beds is better understood than formerly, and we now know that these beds are the field of the most active warfare between the beneficent and the baleful microbes contained in surface water. The fight is somewhat of the same character as that described in the legend of the Kilkenny cats, where both antagonists are destroyed, or at least rendered *hors de combat*, for the eventful result is to deprive the water almost completely of microbes of every sort, the organisms themselves actually stopping their own passage through the filter.

Had this kind of filtration existed and been properly managed at Maidstone and Lynn, no such outbreak of typhoid as these towns have experienced could possibly have occurred.

REMOVAL OF MANURE.

SOME time since a circular communication from the Medical Officer of Health to the County Council was sent to the local Medical Officers of Health stating that the Public Health Committee of the Council, from time to time, receive complaints of nuisance arising from accumulations of manure at various premises in London; also that under Section 36 of the Public Health (London) Act, 1891, the Sanitary Authority is empowered to employ or contract with scavengers "for collecting and removing the manure and other refuse from any stables and cow-houses within their district, the occupiers of which signify their consent in writing to such removal."

In reference to this matter, the Medical Officer of Health, Kensington, states that "the Committee had been advised that the Sanitary Authority has no power to charge for this service, and they were considering the question whether, with a view to facilitating the removal of manure, it is desirable to seek an amendment of this section, so as to give each Sanitary Authority power to charge for the removal of manure, when required by the owner or occupier of any premises to remove it, similar to that which it now has under Section 33 in respect of trade refuse. The Medical Officer concluded by inquiring whether I was in favour of such a proposed amendment of the law. In reply to this communication I stated that in my reports, during many years, I had advocated not only that the Sanitary Authority should have power to remove

accumulations of manure in London districts, but also that in the interests of public health it should be made a statutory duty, and that they should be authorised to charge the owner of the refuse a reasonable sum for the service. As the law stands, the owner or occupier of any premises may 'require' the Sanitary Authority to remove any trade refuse on payment (Section 33), but the Sanitary Authority need only, 'if they think fit,' collect and remove 'manure and other refuse matter from any stables and cow-houses, the occupiers of which signify their consent in writing to such removal'—a consent which may be withdrawn or revoked with one month's previous notice to the Sanitary Authority (Section 36). The owner of such refuse cannot 'require' the Sanitary Authority to remove it; nor is he under any obligation to pay for the removal, although, doubtless, many occupiers of stables would be well pleased to do so, and so, on the one hand, be quit of a troublesome responsibility; and, on the other hand, be freed from liability to fine for neglect of your Vestry's regulations, which require the occupier to remove the refuse on Monday, Wednesday, and Friday, or on Tuesday, Thursday, and Saturday in each week."

It is a question, however, whether the refuse of a cow-house, or an omnibus or cab-yard, may not be classed as "trade refuse," which the occupier of the premises may "require" the Sanitary Authority to remove on payment; certainly fish offal, and the offal from slaughter-houses, comes under the definition of "trade refuse," and it is surprising that fishmongers and butchers do not "require" the Sanitary Authority to remove it.

In the interest of public health, the sooner this matter is put upon a proper basis the better, and we think that Dr. Dudfield is to be commended for bringing the matter to the front.

THE NEW SEWAGE WORKS AT MIDSOMER NORTON.

SOME particulars of these works, which have been recently opened, have been supplied by the engineer, Mr. W. F. Bird. From this description we gather that the process is that of precipitation by chemicals and filtration through artificial beds and land. The sewage on admission to the works passes first through a straining grating, where all coarse matters and foreign bodies are retained, and then through a scum and detritus chamber, which intercepts sand and fatty matters. Next the chemical precipitant (Ferozone) is added, the mixing being done by a "Kierby" machine, the motive power of which is a small water-wheel worked by a portion of the river water which has been diverted for that purpose. After the precipitant is added, the sewage is passed over a series of iron bafflers, which thoroughly mix the chemical with the sewage, and it then enters the first settling tank. This tank is 16ft. in diameter and 10ft. 6in. deep, and the sewage enters at the bottom by a series of vertical inlet pipes, and is discharged from the top by means of wood-collecting channels, and it is found that by this method all the solid matters in suspension are retained at the bottom of the tank. This is removed daily by means of an ingenious revolving steel arm, and is run on to prepared and drained sludge lagoons, where it is dried for removal, the thin liquid portion which is drained off being pumped back into the inlet chamber for re-treatment. After leaving this tank the sewage is run through another of similar design and size, and it is believed the present instance is the only one where duplication of tanks has been carried out, the engineer claiming that by means of it a better effluent is produced at a reduced consumption of chemicals. The tanks are so arranged that the sewage can be run through either of them separately, through both equally, or through one after the other. From the settling tanks the sewage effluent is now run on to the filter beds; these are four in number, each forty square yards in area, and are composed of gravel sand, and a patent filtering medium, known as "Magnetite." Either one or more of these beds can be used at the same time, and by an ingenious system of valves the effluent can be sent through any bed or beds and then brought up through any other bed, for the purpose of washing the top sand with the filtrant, and thus effecting a considerable saving of labour in sand washing. Leaving the works the filtrant is conveyed by a 12in. pipe for a distance of about 600 yards on to the outfall land, situated near Old Welton Colliery. Of this land about four acres has been laid out, channelled, levelled, and underdrained, and, after passing through this, the now purified sewage is discharged into the stream. The engineer for the works is Mr. W. F. Bird, C.E., Surveyor to the District Council; the engineer consulted to report upon Mr. Bird's scheme was Mr. T. S. McCullum, C.E., of Manchester; the contractors for the principal works are Messrs. Thomas and Webb, of Bristol, and for the outfall land works, Mr. W. A. Catley, of Midsomer Norton, and the clerk of works has been Mr. A. B. Carter. The patent sludge removal apparatus was supplied by Mr. Pullen-Candy, of Altrincham, the chemical mixer by Mr. Kierby, of Swinton, the "Magnetite" by the Magnetite Purification Company, of Manchester, and the ironwork and valves by the Glenfield Company, Limited. The cost of the works has been about £2100.

MICROBES AND SANITATION.

MR. F. W. RICHARDSON, the Bradford City Analyst, recently gave, under the auspices of the Bradford Health Association, a lecture on "Microbes and Sanitation." The lecturer, by means of lantern slides, elucidated the subject of the nature and distribution of germs. The principal zymotic and contagious diseases received full treatment, and the diminution of the death-rates was shown to be concomitant with improvements in sanitation. He described typhoid fever as "filth disease," one day to be blotted out through the final abolition of insanitary conditions. Sewer gas was undoubtedly responsible for the spread of typhoid, sometimes directly and in other cases by its potent action in reducing the vital resistibility of the organism. Bad plumbing in the way of defective drains and traps had very much to be responsible for, and the examination and registration of plumbers was a sign of real progress. Tubercular consumption was largely preventable, and the importance of preventing promiscuous expectoration on the part of consumptives was emphasised. The other chief infectious diseases were considered in brief, and the best methods of sanitary prevention were outlined.

Annotations from Annual Reports.

Precautions against the Pollution of Wells.—Reporting on the water supplies of the urban and rural sanitary districts of Taunton, Dr. Henry J. Alford, Medical Officer of Health, says :—"It should never be forgotten that the area drained by a well resembles an inverted cone, and the deeper the well the larger the area drained. The nature, too, of the soil is a most important factor, a sandy or gravel soil, of course, allowing of much easier percolation than a marl or clay. It is surprising how ignorant people continue to be of these simple facts. The situation of the well in relation to possible pollution seems, in many cases, to be entirely ignored. One instance came under observation of a well which it was maintained must be pure, as it was far away from drains in the middle of a garden. It was immediately under a heavily manured asparagus bed, which accounted for its pollution. Another not uncommon means of pollution is the habit amongst cottagers of emptying slops or waste water on the surface above the well, preparatory to cleansing utensils from the pump."

Contracts for Removal of House Refuse.—The drawbacks attaching to short contracts for removal of house refuse are commented upon in the report of Mr. C. W. Hill, Chief Sanitary Inspector, Carlisle. "In October last," he states, "the contract for the removal of refuse was let to a fresh contractor, but on account of having accepted a very low figure for the work, he has only undertaken to remove the refuse for one year, and consequently, next September fresh tenders will need to be procured. This is to be regretted, as changes of contractors at intervals has a tendency to somewhat interfere with the satisfactory collection of refuse owing to the employment of men and horses not accustomed to the work, which disadvantage would be entirely obviated, and a great general improvement effected if the work was undertaken by the Corporation themselves directly, employing their own men and horses."

Alcoholism in Leek Urban District.—The temperance party would evidently find scope for their energies in the Leek Urban District, judging by the report of Dr. J. J. Ritchie, Medical Officer of Health, who states that the deaths from alcoholism during 1897 were larger than he ever remembers seeing recorded in his returns. "Recent scientific observations," he adds, "have confirmed the belief long held by investigators that alcohol is inimical to health by reducing the resisting power of the tissues, and that in small quantities it actually assists in the multiplication and growth of many microbes, and that also in some diseases, at any rate, its administration is not only not followed by any good effect, but exerts a positively deleterious influence on the course of the disease, and nothing is more certain than that alcohol is responsible for a large proportion of the diseases of brain, heart, liver and kidneys observed, and this when taken in quantities far short of actual intoxication. The deaths from diseases of the organs named above are considerably in advance of those reported last year."

THE MUNICIPAL OFFICERS' ASSOCIATION.

LAST week we briefly recorded the fact that the fifth annual meeting of the members of this Association was held in the Council Chamber at Guildhall on Tuesday, the 22nd ult. There was a fair attendance of members. In the absence of the Lord Mayor, owing to indisposition, Mr. Alderman and Sheriff FRANK GREEN presided. In opening the proceedings he extended a cordial welcome to the members. The fact that the present was the fifth annual meeting of their Association indicated, the Alderman continued, that the Institution was one whose objects must, if attained, be of benefit. The Alderman then vacated the chair, a vote of thanks being afterwards accorded to him. Mr. C. WILLIAM TAGG, Vestry Clerk of Camberwell, was then elected to the chair, and moved the adoption of the report, which stated that the past year had been one of great progress, the Association having not only maintained its position, but trebled its membership since the previous report was issued. The Association, the report continued, was now in a position, so long desired, to further develope the aims and objects for which it was formed. The report went on to speak of the question of superannuation, and urged that that matter should be pushed forward as much as possible. The report was adopted.

Mr. JONES, in proposing the Lord Mayor for the post of president, said that their Association, ever since its foundation had been taken, so to speak, under the ægis of what was the greatest Municipal Authority of the world. The Association had a great responsibility cast upon it, and it was essential, therefore, that they should leave no stone unturned to keep it up to a high level. It was manifestly of immense importance to have someone like the Lord Mayor of London at their head, because he represented practically the highest level of municipal life.

The Lord Mayor having been unanimously elected, the following members of the Association were re-elected as vice-presidents :—Mr. G. S. Ager, chairman, M.R.C.A.; Mr. G. Attenborough, accountant, S.B.L.; Sir A. R. Binnie, chief engineer, L.C.C.; Mr. Samuel Brown, town clerk, Salford ; Mr. F. Cooke, town clerk, Crewe ; Mr. G. H. Croad ; Mr. H. H. Crawford, city solicitor ; Mr. John Price, city surveyor, Birmingham ; Mr. H. M. Robinson, LL.D., vestry clerk, Shoreditch ; Mr. A. W. J. Russell, chairman, executive council, 1895—96 ; Mr. S. Southall, town clerk, Worcester ; Mr. C. J. Stewart, clerk to L.C.C.; Mr. M. H. Hale, vestry clerk, Holborn District Board ; Sir Samuel Johnson, town clerk, Nottingham ; Mr. Shirley F. Murphy, Medical Officer of Health, L.C.C.; Mr. C. William Tagg, vestry clerk, Camberwell ; Mr. J. Wilson, clerk, Croydon Rural District Council. Mr. Gilbert Harnden was elected the hon. treasurer, Mr. C. J. F. Carnell, the hon. secretary, and Mr. W. Gunner (Croydon), and Mr. J. R. Thwaites (St. Martin's-in-the-Fields) the auditors. The following re-elections also took place :—Standing parliamentary counsel, Mr. G. A. R. Fitz-Gerald ; counsel, Mr. A. Macmorran, Q.C.; junior counsel, Mr. H. Courthorpe-Munroe ; hon. solicitor, Mr. Matthew H. Hale.

The Lord Mayor being absent, the usual presi-

dential address was not delivered. The CHAIRMAN, however, in a lengthy address, referred to the question of superannuation, and moved the following resolutions :—"That this Association respectfully desires to draw the attention of the Government to the hardships experienced by officials of Local Authorities in the metropolis on account of the permissive nature of the Superannuation Act, 1866, inasmuch as in several recent instances, officials who had after long and faithful services been compelled by infirmity of mind or body to resign office were refused a retiring allowance without any reason for such refusal being assigned, while in the case of other officials substantial allowances were granted ;" and "That the Government be earnestly urged to insert in any Bill now before, or to be introduced into Parliament with reference to local government, a clause providing for uniformity of action by the Local Authorities throughout the country, and making compulsory the granting of retiring allowances (except in cases of dismissal from office for official misconduct) upon the officers contributing a percentage deduction from their salaries." The resolutions were carried, and the election of members of the executive council brought the proceedings to a close.

EDINBURGH SANITARY PROTECTION ASSOCIATION.

THE twenty-first annual meeting of the Edinburgh Sanitary Protection Association was held in Dowell's Rooms, Edinburgh, Sir Douglas Maclagan presiding. The annual report, which was submitted by Colonel Noble, the secretary, stated the Society, during the twenty-one years it had been in existence, had done a great deal of inspection work in both town and country. The balance at the credit of the Society was £3028 2s. 2d. The chairman moved the adoption of the report, and remarked that the Society had always been a philanthropic and not a commercial institution. Mr. J. R. Findlay seconded the motion, which was adopted. In moving a vote of thanks to the chairman, Sheriff Mackay alluded to his eminent services in the cause of the public health, and mentioned that the past year had been an important one in this direction, in that arrangements were being made for the institution of a Chair of Public Health in Edinburgh University, while there had been passed by Parliament the new Public Health (Scotland) Act.

SANITARY HOTELS AT HOLIDAY RESORTS.

CO-OPERATION OF READERS REQUESTED

IN accordance with an announcement made in previous issues of THE SANITARY RECORD, we are prepared to examine and report upon the sanitary condition of Hotels and Boarding Houses at Holiday Resorts, and if the examination is satisfactory, to issue a certificate to that effect. Sanitary Inspectors and others are invited to co-operate with us in this matter, and we shall be pleased to forward particulars to any such who may care to do so. We are not asking for gratuitous assistance, but are prepared to adequately recompense sanitary workers who may interest themselves in our enterprise.

SANITARY HOTELS.

ILFRACOMBE. — Ilfracombe Hotel, H. R. Grover, Manager.

General News.

HOME.

NOTICE.—On and after 31st March next the Annual Subscription to this Journal will be raised to 12s. 6d. to all NEW Subscribers. NO ADVANCE will be made to our friends whose names are entered on our Subcription list prior to that date, so long as they continue to Subscribe.

SWINDON.—It has been decided to erect new baths at a cost of over £5000.

ROMFORD.—The Urban Council has resolved to invite competitive plans for the erection of public baths that are not to cost more than £4000.

NOTTINGHAM.— Mrs. Longshore-Potts, who, it will be remembered, lectured with much success in Nottingham two years ago, commenced a series of five afternoon lectures on women's health on Monday, February 28th.

RYTON.—Owing to an epidemic of measles which is prevailing in the district, several of the schools have been closed for the present, on order of the District Council. The schools in the meantime are being throughly disinfected by the Inspectors.

CUCKFIELD.—The Rural District Council has resolved to apply to the Local Government Board for a loan of £60,000 for the purchase of the Mid-Sussex waterworks, together with the necessary expenditure for the proposed extension of the works.

LLANDUDNO. — A Local Government Board inquiry has been held into three applications by the Urban District Council for powers to borrow £8634 for water supply works, £3580 for gasworks purposes, and £1395 for a site for workmen's dwellings.

LEEDS.—The Corporation Baths Committee, at a recent meeting, decided to recommend the City Council to apply for powers to borrow £23,000 for the purchase and renovation of the Oriental Baths, Cookridge-street, now the property of a private company.

EASTBOURNE.—A Local Government Board inquiry has been held as to a petition for a Provisional Order by the Corporation, empowering the Council to apply the Lands Clauses Acts with respect to the purchase and taking of lands otherwise than by agreement, which are required by the Corporation for the extension of the borough hospital, and for purposes of street improvements.

STIRLING.—A public meeting was held recently in Stirling for the purpose of inquiring into the sanitary condition of the town, with special reference to the epidemic of scarlet fever, which has been prevalent for some time past, but which is now subsiding. During the course of a lengthy discussion, a number of questions regarding the health of the burgh were put and partially discussed, but as it was deemed advisable they should get more particular attention, and the Local Authority given an opportunity of answering them with authority, it was agreed that a deputation of ten gentlemen be appointed to wait on the Public Health Committee of the Town Council and lay the matters before them.

WINSFORD.—At a recent meeting of the Urban District Council it was reported that there was a serious outbreak of measles in the town. Over 100 children were absent from the Board School through the prevalence of the disease. The Medical Officer of Health pointed out that prompt action was necessary, and the Council decided to close the school for three weeks and take other necessary steps to prevent the spread of the disease.

MANSFIELD.—At a monthly meeting of the Town Council it was decided to lay new water-mains at a cost of £270, and to extend a sewer at a cost of £100. As the enlargement of the swimming bath would cost £750, it was decided to postpone the question for the present. It was resolved to lend £3000 to the Mansfield Woodhouse Urban District Council at 3 per cent., for the purpose of carrying out the works of water supply.

HEANOR.—For some time past the Council has been somewhat perplexed in regard to the water scheme which it started last midsummer at Smalley. It appears that owing to some misunderstanding with the owner of the land, Mr. R. S. W. Sitwell, the operations at the works ceased. It was explained at a recent meeting that Mr. Sitwell required £600 to be deposited with the Belper District Council as security in payment of costs for laying mains, in accordance with an agreement made by Heanor Council in October, 1896. After some discussion it was resolved that the sum of £600 should be deposited with Belper Authority; also that the purchase of the land should be completed on those terms.

CARDIFF.—At a recent meeting of the Health Committee of the Corporation, the borough engineer, Mr. W. Harpur, presented plans for the extension of the sanatorium. The plans provided for the erection of three pavilions, similar to the present structures, and there will be accommodation for sixty extra beds. The cost is estimated at £24,000. In reply to questions, Dr. Walford, the Medical Officer, stated that there would be no extra provision for isolation, but if the new buildings were erected the whole of the present isolation hospital could be used, and this would be ample. At present there were seventy-two beds, and the new pavilions would contain another sixty beds. The plans were inspected, and afterwards passed, and the Committee is now in a position to apply for a loan for the required sum.

BATTLE.—At the last meeting of the Urban Council the Water Committee reported that on account of the exceptionally dry winter and the non-breaking of the springs, the old well had given out and they had to trench upon the resources of the new well. They had therefore found it absolutely necessary to issue notices to consumers asking them to exercise every care to prevent waste. The chairman said it was a most serious matter, and if the Council had been free from loans, he should advocate going at once for a good additional supply. This was the second year of drought, and the want of water was being felt almost everywhere. Their present supply was not artesian, but simply by percolation. He did not think they ought to allow the question to remain in abeyance till they were forced to take action. He would be pleased to make a survey with some of the members, with the object of finding an additional supply.

ABROAD.

JOHANNESBURG. — The Town Council has selected a site for proposed destructor. The area is 3½ acres and the price fixed is £25,000. The matter has to be confirmed by public meeting which is to be held during this month.

RICHMOND (N.S.W.)—The analysis of water taken from the Richmond water supply reveals an unsatisfactory state of things. The Board of Health recommends, among other things, the filtration of the water before it enters the reservoir. A special meeting of the Municipal Council has been called to deal with the matter.

ASHFIELD (N.S.W.)—Typhoid is still very prevalent in the borough of Ashfield. The Council has just completed the construction of the drain across the Parramatta-road, through Dobroyde. This will afford an escape for the accumulation of what was formerly little better than a swamp, and a serious menace to the residents of the locality.

Personal.

MR. CRAYTHORNE has been reappointed Sanitary Inspector for the district of Paignton.

MR. M. GEPP has been appointed Medical Officer of Health for the borough of Shrewsbury.

Mr. G. R. GREEN has been appointed Medical Officer of Health for the borough of Ripon.

MR. S. ANDREWS has been appointed Medical Officer of No. 2 district of Basingstoke union.

MR. J. F. HOLDEN has been appointed Medical Officer for the fourth district of Preston union.

MR. T. G. DICKSON has been appointed Medical Officer of Health for the rural district of Hay.

MR. J. T. JONES has been appointed Medical Officer of Health for the rural district of Llansilin.

MR. P. H. NUTTING has been appointed Medical Officer for the third district of Malmesbury union.

MR. J. H. PEET has been appointed Medical Officer for the No. 8 district of Basingstoke union.

MR. C. B. TRUMPER has been appointed Medical Officer of Health for the urban district of Market Rasen.

MR. T. G. DICKSON has been appointed Medical Officer of Health for the rural district of Painscastle.

MR. A. ST. L. BURKE has been appointed Medical Officer for the Bushbury district of Cannock union.

MR. T. G. DICKSON has been appointed Medical Officer of Health for the rural district of Bredwardine.

THE salary of Dr. Monk, Medical Officer for Leicester, has been increased from £500 to £600 per annum.

MR. J. P. WAKEFORD, A.M.I.C.E., M.S.I., assistant for the past five years in the office of the city surveyor and waterworks engineer, Dublin, and formerly assistant in the office of the city engineer of Belfast, has been appointed assistant waterworks engineer to the Corporation of Harrogate.

MR. H. L. THURRELL has been appointed Medical Officer of Health for the borough of Gravesend.

MR. H. M. WISE has been appointed Medical Officer of Health for the Plumstead district of Woolwich union.

MR. E. T. PRIOR, of Loddon, has been re-appointed Medical Officer of Health for the rural district of Loddon and Clavering.

MR. J. T. GRIFFIN has been appointed Inspector of Nuisances, and Mr. S. J. Taylor, Medical Officer of Health for the urban district of Chingford.

THE Battersea Vestry has decided to increase the salary of Miss Bertha Thurgood, Sanitary Inspector, to £101 per annum, rising to £150 per annum.

MR. J. S. HIGHFIELD, of Stafford, has been appointed resident Electrical Engineer for the St. Helens Corporation, at a salary of £200 per annum.

THE Local Government Board has sanctioned the reappointment of Dr. Sanderson as Medical Officer of Health for Hastings, at the reduced salary of £20 per annum, on account of the smaller area.

MR. JAMES SAUNDERS, assistant Surveyor of Oldham, has been elected City Surveyor and Water Engineer of Chichester. Mr. Saunders is a graduate of the Incorporated Association of Municipal and County Engineers, an Associate of the Royal Institute of British Architects, and an Associate of the Manchester Society of Architects, and he has had considerable experience in carrying out the large engineering and architectural works recently constructed by the Oldham Corporation.

Sewerage Schemes.

[TO MUNICIPAL ENGINEERS AND SURVEYORS.—The Editor will be pleased to receive items for publication relating to sewerage schemes projected or inaugurated, together with explanatory diagrams or photographs. The former should be drawn and lettered in black ink.]

THE plans of the Saxmundham drainage scheme have been sent to the Local Government Board.

THE new contract for laying a sewer along foot of Garden-road to West Port, Newburgh, has been commenced by Mr. William Barlow.

NOTIFICATION of objection to the Glasgow Corporation (Sewage, &c.) Bill has been lodged in the House of Commons on behalf of the Commissioners of Clydebank.

A LOCAL Government Board inquiry has been held at Hurstpierpoint in respect to a petition presented by the Council to the Local Government Board, asking it to empower the Council to put in force, with reference to certain lands required by it for the purpose of the disposal of the sewage of the parishes of Hurstpierpoint, Keymer, and Clayton, the powers of the Land Clauses Acts, with respect to the purchase and taking of lands otherwise than by agreement.

A LOCAL Government Board inquiry has been held at Tingley relative to an application of the Ardsley East and West Urban District Council for sanction to borrow £2900 for sewerage works.

THE Tutbury Rural D istrict Council has instructed Mr. J. E. Willcox, C.E., of Birmingham, to prepare a scheme for the sewerage and sewage disposal of the parish of Branstone, within the district of the Council.

THE Local Government Board has sanctioned a loan of £4500 for works of sewerage and sewage disposal at Aldridge, and at a recent meeting of the Walsall Rural District Council Mr. J. E. Willcox, C.E., of Birmingham, was instructed to at once proceed with the scheme.

A LETTER has been received from the Local Government Board with respect to the application of the Portishead District Council for sanction to borrow an additional sum of £3000 for works of sewage, and requesting that the Board should be supplied with additional particulars from the Council respecting the same.

THE question of the Clewer drainage scheme was brought forward at the last fortnightly meeting of the Windsor Rural District Council. The Local Government Board propose to hold, on March 15th, an inquiry into the matter of obtaining by compulsory powers a piece of land at Clewer for the purpose of erecting a pumping station.

AT the last meeting of the Stonehaven Police Commission, a recommendation from the Finance Committee, to the effect that the Commission borrow from the Town and County Bank the sum of £1400 in connection with the water and sewerage operations in the Slug-road, and £1650 in connection with the lodging-house, was agreed to.

A SPECIAL meeting of the Keith Burgh Commissioners was held recently for the purpose of considering Dr. Aitken's report on the waste products of the distilleries and public works within the burgh. The report was read by the chairman, and all the details were then carefully considered. After some discussion, it was agreed to admit into the proposed sewerage scheme the waste products from these works under certain conditions, these conditions to be afterwards specified and submitted to the owners for approval.

AT a recent meeting of the Wishaw Commissioners an exhaustive report, prepared by the burgh engineer (Mr. Tait) on the diversion of the outlet drain at Craigneuk, owing to the Lanarkshire Steel Works extension, and on the present condition of the sewerage when it enters the river Clyde at one point, and Calder water at the other, was rejected. The outlet to be disused was about 25ft. deep, and was put in twenty years ago. The report proposed diverting the outlet to a junction with the main outlet near Carbarns, two miles distant, the cost being £2050. The report was favourably received.

THE names of the Royal Commission on the unsavoury but important subject of sewage disposal in the large towns will shortly be stated to Parliament. It will be a Committee mainly of experts on hygiene and the disposal of sewage.—*Daily News.*

AT a recent meeting of the Isle of Thanet Rural District Council, Mr. E. Bailey-Denton's report for estimate for sewerage and sewage disposal of Minster was submitted for consideration. The report dealt exhaustively with the proposed scheme, which provides for the requirements of a population of at least double the present population of the area dealt with. The report and estimate having been considered, it was decided that the District Council should meet, and that the Minster Parish Council be invited to join them to inspect the whole area to be drained. It was also decided to ask Mr. Bailey-Denton to be present and give any information required.

A SPECIAL meeting of St. Andrews Town Council was held last week for the purpose of considering the question of drainage outlets. The clerk (Mr. Grace) read a long report on the subject prepared by Mr. W. P. Brenan, Oban, which had been provisionally approved by a committee having charge of the matter. In the report, Mr. Brenan proposed the construction of a 371ft. iron sewer at a cost of £442; a sedimentary tank to be placed at the seashore, £1438; pumping station, with single engine and pump pipes and well, £266; gravitation sewer from Rathelpie to City-road, £386; engineering and contingencies, £254; making a total of £2786.

THE Committee of the Manx Legislature appointed in the matter of the application by the Douglas Corporation for power to borrow £20,000, in addition to £35,000 already authorised for the improvement of Douglas sewerage, sat on Wednesday, the 23rd ult. The application was opposed by a number of ratepayers, who objected to the mechanical system proposed. Mr. E. H. Stevenson, engineer, London, the designer of the scheme, stated that the only reason that existed for the mechanical system was that certain basements were below the tidal level. If these were not to be drained a gravitation system would be better and cheaper. The inquiry was adjourned to allow a gravitation scheme to be submitted.

FOR some months past the condition of the drainage at the Islington Parochial Schools has engaged the earnest attention of the Guardians, and on more than one occasion members of the School Committee have asserted most positively that the drainage is perfect. A slight outbreak of enteric fever among the children has led to an exhaustive inquiry being made, with the result that one of the latrines was found to be not only in a defective condition, but to have no outlet at all. It had also been rumoured in some quarters that an old sewer runs directly under the school buildings. Notwithstanding all that has been said upon the question of the drainage of the schools, experts are at present unable to state that it is in absolutely sanitary condition.

Lighting.

THE Belfast Corporation has decided that the extension of the lighting of the Knock and Sydenham districts be proceeded with without further delay.

AT a recent meeting of the Lancaster Town Council it was resolved to apply for powers to borrow £10,000 to increase the electricity plant so as to double the output.

THE Corporation of Aberystwith has notified its intention of opposing the Gas Bill by counsel when the Committee stage is reached in the House of Lords.

THE Electric Light Committee of the Dublin Corporation has decided to advertise for tenders in connection with the laying of the new cables for the electric lighting of the city.

AT a recent meeting of the Drogheda Corporation a resolution was passed approving of the action of the Gas Committee in arriving at an agreement with the Gas Company to purchase the works at £21,000.

THE Loughborough Town Council has decided to appoint a committee to report on the advisability of taking steps to acquire the gas undertaking, and also to obtain information and report on the question of establishing electric light in the borough.

THE Electric Lighting Committee of the Greenock Council reports that the probable cost of lighting the burgh would be, roughly, £95,000. The report also indicates that the most suitable place for the installation would be the Water Trust property at Prospect-hill.

AT a special meeting of the Sheffield City Council last week the matter of the purchase of the undertaking of the Sheffield Electric Light and Power Company by them came up for consideration. At the meeting on the 9th ult., the terms of purchase as submitted by the company were agreed to, but it was done in such a way that a day or two after a letter was received from their solicitor saying that the directors had decided to suspend the negotiations for the sale for the present. Thereupon the Parliamentary Committee met, and passed a resolution expressing regret that the negotiations had been suspended, and fully acquitting the directors of any improper secrecy or conduct in the matter. The reply from the solicitor to the company was to the effect that if the Council endorsed the apology of the Committee, the negotiations would be allowed to proceed. The terms of purchase are that the Corporation shall pay for every £100 of capital properly expended £220 in 2½ per cent. redeemable stock, or £213 8s. in cash.

LARGE new condensers and scrubbers have just been erected at the Pitlochry Gas Works by Messrs. Balfour and Co., Ltd, Leven, and were put in use for the first time last week, when they were found to work very satisfactorily. It is understood that considerable extensions are to be made to the works this year, owing to the rapid increase in the consumption of gas.

THE Electric Lighting Committee of Edinburgh Town Council recommends the laying of a new feeder from Dewar-place along Grove-street, and out to Merchiston, at a probable cost of £1400. On the recommendation of the same Committee, the Council has agreed to accept an offer of £1100 from William Clowes and Sons, London, for the purchase of two engines and dynamos at the central electric lighting station, for the use in which they had become too small.

THE Town Council of Stirling having some time ago requested Professor Kennedy to report further as to the practicability of utilising the water power at Touch for the electric lighting of the town, his report was submitted to a recent meeting of the Council. He finds that the maximum theoretical hydraulic horse-power of the water coming into Stirling from No. 3 reservoir is 26; from No. 4 reservoir, 7; and from the Touch compensation water, 7—in all, 40 theoretical hydraulic horse-power. The actual amount of this horse-power in the mains at Stirling for supplying light would not be more than half of this amount, however, and it might be considerably less. The total horse-power provided in his steam-power estimates was 320, which would, after making all allowances, deliver at least 233 electrical horse-power at the lamps. The total cost of this plant would be between £8000 and £8500.

THE Tramways Committee of the Liverpool City Council recently had under discussion a scheme formulated by Mr. Holmes, city electrical engineer, for the construction of two generating stations to supply the whole city with electrical energy for lighting, tramways, and power purposes. Dr. Hopkinson, the consulting electrical engineer, approves of Mr. Holmes's proposal of combined stations for generating, anticipating 5 per cent. saving in cost of plant, although no great economy in coal and wages. There would be an advantage in the reserve machinery being available for either services. The Lighting Committee and the Tramways Construction Committee, who have considered the scheme, recommend that the existing electric lighting stations remain under the control of the Lighting Committee, and that the power stations to be hereafter provided be managed by a special committee to be appointed, and including eight members of the Lighting Committee, and eight of the Tramways Committee, and that the erection of additional generating stations be considered by the joint special committee. If thought convenient, new borrowing powers will be applied for to raise money to erect two new generating stations at an early date, Pumpfields being suggested as a suitable site for the first station.

THE Holborn Guardians have passed a resolution protesting against the proposed increase in the price of gas by the Gas Light and Coke Company, and requesting the Guardians of other unions and parishes situate in the area supplied by the company to join in the protest.

COVENTRY is taking to the electric light with increasing kindness. The annual report of the Corporation's Electric Light Department shows that the number of consumers increased during the year 1897 from 72 to 100, and the lamps connected from 5662 (8 c.p.) to 8149. Further connections are being made.

Sanitary Inspectors' Associations.

CARNARVONSHIRE.

ON Saturday, the 19th February, at the Guildhall, Conway, a conference of this society was held, Dr. Fraser, Medical Officer of Health for the county, in the chair. The Association resolved to amalgamate with the North-Western and Midland Association. The annual balance sheet, which was considered very satisfactory, was read and adopted. Officers were elected as follows:—Dr. Fraser, president; Mr. E. Worrall, Penmaenwawr, chairman of council; Mr. J. P. Davies, Carnarvon, honorary secretary. The morning meeting closed with a vote of thanks to Dr. Fraser for his valuable services to the society, moved by Dr. Prichard and seconded by Mr. J. Jones, Conway. At the afternoon sitting, Dr. G. Read, Medical Officer of Health for Staffordshire, gave a lecture on "The Principles of House Drainage," the lecture being illustrated by numerous diagrams and models.

Houses Let in Lodgings.—Mr. William Kelso, Chief Sanitary Inspector, Paisley, alludes in his report to the difficulties which attach to this branch of his work. People occupying small houses hardly sufficient for their own requirements—in many cases insufficient—take in lodgers. The common excuse is "that they are friends and are not payng as lodgers." In other cases a room or two is let "to make a little money." Such cases could be dealt with under Section 16 of the Public Health Act, but the procedure is not only cumbersome, but fails in effect. A much more simple summary and effective procedure is to register such houses as "houses let in lodgings," which, it must be observed, extends to "houses occupied by members of more than one family." This brings them under regulations which can easily be enforced, if properly understood and appreciated. In Paisley thirty-five such houses were registered during the year, and twenty-seven of these were over-crowded by from one to five adults. The total number on the register at the end of the year was eighty-one, and twenty-seven of these remained overcrowded, notwithstanding the efforts of the Inspectors. Although proceedings were taken against two of the worst offenders, who were convicted and fined in sums of 2s. 6d. and 5s. repectively, this was evidently looked upon so lightly that it had no deterrent effect on the others.

THE RENOVATION OF BOMBAY.

WE abstract the following interesting particulars from an important article which appeared in *The Engineer* for February 25th :—

On previous occasions we have announced to our readers the steps taken in the movement on foot for the improvement of the city of Bombay, and the proposals of the Government in this matter. We are now in possession of the draft of the Bill before the Legislative Council of the Presidency which embodies these objects, and the new Act entitled "The City of Bombay Improvement Bill, 1898," has probably by this time become law. There is no city in India, and probably there are few in the Empire, in which the population is so densely packed as in Bombay, and the overcrowding, both by buildings and of the residents in them, is a standing menace to health. As long ago as 1864, Dr. A. H. Leith, a pioneer in sanitation, and Health Officer of the island, recommended that advantage should be taken of the health-giving sea breezes to ventilate the town by opening up broad avenues through the dangerously overcrowded localities running from the sea-shore on the west towards the east.

Again, in 1887, a committee reported that a series of roads were necessary so that the town and island might be traversed by the prevailing winds with the least possible interruption. But little then could be done where the evil is most serious, except in the way of occasional "set-backs," owing to the ban placed on the action of the Corporation through financial considerations. Of late the evil of overcrowding has become intensified, and from 30 to 40 per cent. of the population is concentrated in areas forming only 3 or 4 per cent. of the area of the island, the density of population being in places even more than three times that of the most crowded areas in London, and over large sections the ground area is under ten square yards per individual. It is not to be wondered at that in these circumstances the total mortality, which for the whole city averages 40·71 per mille, is reported to have reached in the crowded localities a rate per mille varying from 52·15 to 68·09.

This was in 1896, just before the bubonic plague had developed itself as an epidemic. As soon, however, as the plague assumed this character, the necessity of action became accentuated, for the heavy mortality soon reacted disastrously on trade and commerce. It was found that the chief condition influencing the occurrence and spread of the scourge in certain localities, was defective ventilation and density of population. Overcrowding made inspection, the detection of cases, and the proper application of sanitary remedies impossible. Searching investigation into the sanitary conditions, which followed, brought prominently into notice a very large number of dwellings which, besides being dangerously overcrowded, were highly insanitary, being defective in ventilation and so shut in as to be deprived of light and air that they were in many cases wholly unfit for human habitation.

With a view to remedying effectually these conditions, the Bill provides for the improvement of the city by forming new, and modifying existing streets, by removing or altering insanitary buildings, by providing open spaces for better ventilation and for recreation, and by constructing new sanitary dwellings for certain classes of the inhabitants of the city, and quarters for the Presidency police, who now find proper accommodation impossible of attainment. It is found, moreover, that it will be possible by suitably aligning the new streets, so urgently necessary for the improved ventilation of the city, to take up a large proportion of the insanitary dwellings as either part of the street or as frontage lands abutting thereon.

These projects for improvement and purification of densely-crowded localities will, as a matter of necessity, displace a considerable portion of the population, and to provide for this it is intended to fill in and lay out by constructing roads, &c., extensive tracts of vacant land to the north of the city, and to provide thereon, either through the proposed Trust or by private agency, or both, improved dwellings. These vacant lands are scheduled in the Bill, and are situated in the vicinity of the lines of existing or proposed railways, and can be served by extensions of the tramways so as to possess easy means of communication with business and industrial centres.

During the last twenty-five years a very large area of land in the aggregate has been built upon, and there has been an enormous development in the provision of dwellings of a superior class. This activity still continues, and it is remarkable that in many instances costly residences have been erected on restricted and unsuitable if not insanitary sites. The Government therefore propose to hand over certain vacant lands—scheduled in the Bill—their property and suitable for the purpose ; and the Bill accordingly makes provision for the expansion of the city by acquiring and laying out vacant lands, and reclaiming and laying out parts of the foreshore of the island. These portions of the foreshore on the west side of Colaba and Walkeshwar can be reclaimed at no great cost, owing to the natural level being considerably above low-water mark.

The sites thus made available will be well adapted for residential purposes, and will extend over long reaches of sea front with a westerly aspect, those at Colaba being near the business centres, and those at Walkeshwar no further away than the sites recently taken up in such numbers in the same locality. The experience of the Port Trustees has shown that reclamations in such circumstances can be effected at remunerative cost ; that sites made available on such reclamations, when properly laid out, command a ready market, and are profitable for the investment of capital in building.

The duty of carrying out the provisions of the Act is, as we have stated previously, to be vested in a Board of Trustees. This Board is to consist of thirteen members—three *ex-officio*, six elective, and three nominee trustees, with a chairman appointed by the Government. The Bill, after the first two or preliminary sections, is occupied with the constitution, salaries, duties, and powers of the Board. We shall shortly notice some of these matters.

The course of action with regard to the Improvement and Reclamation schemes is similar. On the Board being satisfied by official representation of the unhealthiness of a district or area, it may make a scheme for its improvement. This official representation embraces a wide range of interests ; either the Government itself or the Corporation of the City, through the Commissioner

— presumably the Municipal Commissioner — or even directly by the taxpayers themselves.

The scheme, when duly prepared with accompaniments in the shape of plans and estimates, and after due public notification, is to be submitted to Government for sanction with certain accompaniments. When sanctioned, a declaration under the signature of the Secretary to Government is to be published in the Government *Gazette*, after which the Board may proceed with the execution of the scheme. The interests of the public in the matter of construction by the Board are placed under the guardianship of the Municipal Commissioner, and it is decreed that the streets for carriage traffic are not to be less than 40ft., or if for foot traffic not less than 10ft.

THE VACCINE LABORATORIES OF GERMANY.

THE vaccine laboratories of Germany are under Government control. The percentage of successful vaccination in Berlin is 96·84; in Hamburg, 94·85. The best laboratory in buildings and equipments is that of Cologne. At Hamburg vaccination of 1700 primaries with "germ-free" lymph gave eight cases of skin eruptions. The Imperial Berlin Commission recently reported that, in its judgment, inflammatory appearances are due (1) to the condition of the person vaccinated; (2) to the greater or less amount of effective lymph in the material applied; and (3) to the technic employed in the inoculation. The Commission stated that inflammatory complications are especially frequent if the incisions made in the inoculation are numerous, long, deep, and close together.

It is a familiar fact that inflammation is more frequent in secondary than in primary vaccination. It is also unfortunately the case that a number of German reports state that quite enough disinfection of the arm by means of sublimate solution and ether before vaccination does not prevent all inflammatory complications, but in some cases has actually seemed to increase them. Nevertheless it has been a great advantage to vaccine production that practically "germ-free" lymph may be obtained; because the germs present, while as a rule non-poisonous, are, it is thought, injurious to the vaccine organism, and it is a fact that by employing "germ-free" lymph the so-called "purulence" in the producing animals, one of the former bugbears of the vaccine laboratory, has practically disappeared.

Laboratory workers have about come to the conclusion that it is at present impracticable to produce a sterile vaccine, but two different and partially effective methods of bringing down the number of germs have been discovered. One method consists of centrifugalisation of virus which has been diluted with water; and the second, of mixing the virus with varying proportions of glycerin. The former method reduces the number of bacteria present, but does not entirely remove them; the latter is much more effective, and by means of it the number of germs in lymph, as tested by making cultures on agar, can always be materially reduced within a period which varies from a few days to a few weeks. Sometimes this does not secure sterility, but when old glycerinated virus is not sterile the inference simply is that the germs present are such as resist the action of glycerin; the bacillus subtilis, for instance, which is non-pathogenic, is unaffected by glycerin.

It may then be fairly stated that lymph practically, although not absolutely "germ free," can be secured with considerable certainty. The results from the use of this so-called "germ free" lymph, whether absolutely sterile, have not, however, secured freedom from the inflammatory complications of vaccine. On the contrary, it is the general testimony given by those who have experimented at length with such lymph that inflammatory reactions occur in about the same proportion of cases as before this lymph was introduced, and also that not merely inflammatory complications are present, but occasionally vaccinal eruptions as well, as has already been stated above regarding the Hamburg experiments. Finally, it should be added that while every brand of vaccine has its own bacterial flora, the few germs which are common to almost all are very clearly non-pathogenic to men or animals. Repeated inoculations of germ-bearing lymph have been made in guinea-pigs, rabbits, and other test animals, and almost invariably without any pathogenic results.

Law Cases.

IMPORTANT DECISION AFFECTING PLUMBERS' APPRENTICES.

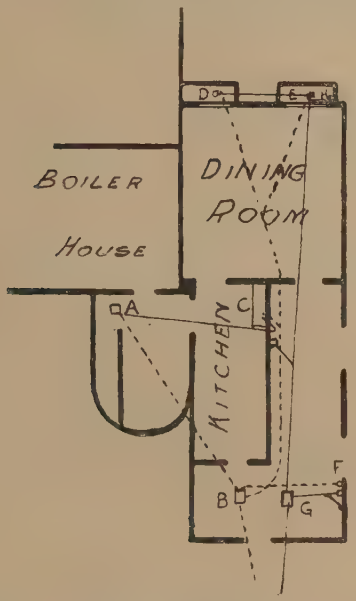
IN the Chancery Division of the High Court of Justice an application was recently made that the apprenticeship deed of a ward of Court should be settled by the Plumbers' Company, and a form drawn up by the Company has been approved by the Judge, Mr. Justice Romer. In addition to the usual provisions based on the indenture for apprentices in the City of London, approved by resolution of the Court of Common Council, April, 1889, special covenants were inserted "binding the apprentice to diligently attend evening classes of technical instruction as directed by the master, under penalty of a reduction in wages, and binding the master to provide for attendance of the apprentice at the courses of instruction and the examination in knowledge of sanitary plumbing and workmanship prescribed by the Plumbers' Company or any statutory body empowered to keep a register of qualified plumbers." These covenants were introduced with the object of encouraging and promoting the apprentice's efficiency, and are novel in the practice of the City of London and the Court of Chancery.

Notes and Queries.

982. — DRAINAGE OF A PUBLIC INSTITUTION: METHOD.—"C. B. M." writes:—"I should be much obliged for your opinion upon the plan of drainage submitted herewith of the cellars and basement kitchens of a public institution. Will you kindly advise whether you consider the proposed method satisfactory, or do you suggest any alteration?"

Answer.—The mode of drainage as proposed is not satisfactory. Our correspondent's plan should be modi-

fied, and we advise him to carry out the drainage on the lines shown by us on the plan which we reproduce. The dotted black lines show our correspondent's proposed method. We must point out that drains should be laid as far as possible in straight lines from point to point, and that a fresh air inlet be always provided to the disconnecting trap or disconnecting chamber, whichever be used, and that an outlet shaft be carried up at the highest point of the drain to the roof of the building. In addition to this, where drains run under buildings, they must be surrounded with Portland cement concrete,



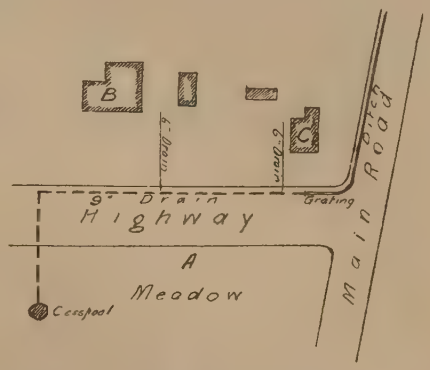
of a thickness equal to the full diameter of the drain, and adequate means of ventilation must be provided in connection with such drain at each end of the portion as is beneath the building. The joints of the drain should be made of neat Portland cement, and before the pipes are covered they should be tested for soundness by the hydraulic or water test. Our correspondent would derive benefit from a careful study of Spinks' "House Drainage Manual," price 5s., obtainable from the Sanitary Publishing Company.

The plan of basement is reproduced, showing in dotted lines correspondent's proposed mode of drainage. The proper mode of drainage, suggested by us, is shown by continuous thin lines.

References.—G, disconnection chamber with trap and fresh air inlet, carried by means of pipes against wall. A, well, with overflow pipe to open air, to discharge over a trapped gully. C, sink, with waste pipe discharging in the open air over a trapped gully. D, gully in area, drain from which is made to discharge over gully E in area. E, gully in area receiving also drainage from gully D in other area. F, rain-water pipe made to discharge over a trapped gully. H, ventilating shaft.

983.—NUISANCE FROM OVERFLOWING CESSPOOL.—"Judex" writes:—"Will you kindly advise me who is responsible for the abatement of a nuisance from an overflowing cesspool, under the following circumstances:—A, the owner of land shown on sketch, complains of a nuisance on his land caused by a cesspool overflowing, into which B and C drain. The Local Authority call upon A to abate the nuisance himself, as existing on his own property and by his sufferance. A refuses, and B is served with a notice. B refuses to do anything on the ground (1) that B and C have an easement in A's property. (2) That the surface water drain in road is a sewer, as it receives the drainage from B and C. (3) That even assuming B and C to be responsible, they have no right to trespass on A's land to cleanse the cesspool. There is no question as to the nuisance, or of the highway drain having been originally constructed for surface water only. You will observe that the cesspool receives not only sewage, but the surface water from the high road."

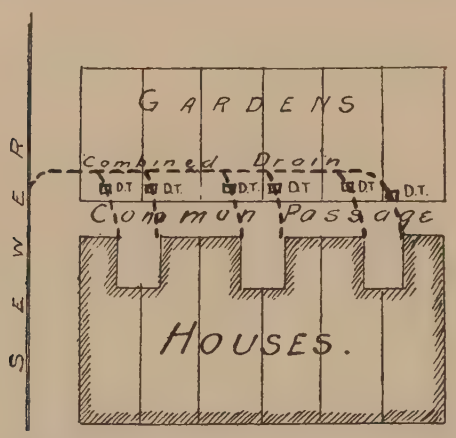
Answer.—We are of opinion that the Local Authority will not be enabled to enforce the cleansing of the cesspool upon A. It is not stated by whom the cesspool was originally constructed. If it was constructed by the Highway Authority for the purpose of receiving surface water from the road, the duty of cleansing the same will, we think, devolve upon the Sanitary Authority. It must be observed that a cesspool has been held not to be a sewer, in Meader *v.* West Cowes Local Board (61



L. J., Ch. 561; L. R. 3, Ch. 18). In that case several houses drained by one common drain into one cesspool, from which was an overflow crossing, without licence, the land of a neighbour, who blocked the overflow pipe, causing the sewage to dam back on plaintiff's land. It was held that neither the cesspool nor the overflow pipes therefrom were a public sewer, and that the duty of abating the nuisance caused by the overflow devolved upon the plaintiff, who was the owner of the land whereon the cesspool existed and of the houses. In the case named by our correspondent the circumstances are somewhat different, inasmuch as the sewer in road is virtually a public sewer used for the purposes of road drainage, and, if we understand rightly, permitted to be used by the Local Authority for receiving sewage in addition. Under the circumstances we are of opinion that the Local Authority would not be able to succeed in attempting to enforce the abatement of the nuisance on any one of the owners concerned.

984.—COMBINED DRAINAGE: DRAIN OR SEWER.—"B. G. B." writes:—"The Surveyor has compelled a builder to provide intercepting traps upon each house drain of a row of houses before they join a combined drain running through the gardens at the rear, and joining the sewer in street at end of row. The houses and land all belong to one man at present, namely, the builder. Query: (1) Is the combined drain a drain or sewer? The intercepting traps placed in the position named appear to point to its being a sewer; but as it is upon private property, I do not think the Sanitary Authority have any right of access, except in case of nuisance, or to make connections to it. (2) In the likely event of houses being sold to separate individuals, I presume it would become a drain, repairable by all users in determined proportions, as provided by Sec. 19 of the Public Health Acts Amendment Act, 1890. If it is a sewer under (1), and a drain under (2), it appears that whether it is a drain or sewer depends absolutely in such cases upon the ownership of the houses, and that what is a drain one day may be a sewer the next, or *vice versâ*. Am I correct in this interpretation? Sketch plan is submitted."

Answer.—(1) We are not informed whether the houses are being newly erected, but conclude that this is the case. It has been repeatedly decided that a drain receiving the drainage of two or more houses is a sewer within the definition of Secs. 4 and 13, and that by Secs. 15 and 19 of the Public Health Act, 1875, the Local Authority are required to keep such sewers in repair. But in Seal *v.* Merthyr Tydfil District Council (61 J. P., 551) the Queen's Bench Divisional Court (July 11th, 1897), decided, on appeal from the magistrates' decision, that a combined drain receiving the drainage of twenty houses, and which combined drain ran through private gardens, and was connected with the sewers of the Council, could not be held to be a sewer until it came out of private property into public streets, so that the world at large could drain into it. A Local Authority have an implied right of access on lands for the purpose of examining or repairing sewers; and in case of refusal they may, as provided by Sec. 308 of the Public Health Act, 1875, after written notice to the owner or occupier, apply to a court of summary jurisdiction for an order authorising them to enter, examine, and lay open the said lands and premises for the purposes aforesaid. (2) The points mentioned by our correspondent are such as have been found



by experience to render the provisions of Sec. 19 of the Public Health Amendment Act, 1890, very difficult to put in operation.

985.—Trapping of Soil Pipes.—Disinfectants.—"Negus" writes:—"Will you kindly answer the following questions:—(1) Do you approve of a soil pipe being trapped at the foot when the closets emptying into the same are not efficiently trapped? (2) Will a D trap syphon? (3) In what proportion would you use corrosive sublimate to disinfect the excreta of a typhoid patient?"

Answer.—(1) Providing the house drain is properly trapped and disconnected from the sewer or cesspool in conformity with the requirements of the Building Bye-laws (Model Series), we do not advise the provision of a trap at the foot of a soil pipe. Where, however, there is no disconnecting trap on the house drain, it is advisable to have a trap with fresh air inlet at the foot of the soil pipe, rather than incur the risk which is ever present of sewer gas finding its way into the house by means of the water-closet, the trap of which may become unsyphoned or defective. Moreover, should the water-closet at any time require repair and the trap to the water-closet be removed, sewer gas has an unobstructed access into houses. (2) A D trap will not syphon under ordinary conditions, and it is only possible owing to exceptional conditions, such as when a piece of rag or absorptive paper may hang over the lip of the trap, one end being immersed in the trapping water and the other end falling over the lip, thus acting by porosity to drain off the water below the water-seal level. (3) For the disinfection of excreta from typhoid patients corrosive sublimate should be used in the proportion of 1 in 500 (one grain to one ounce of water). The solution is one, however, which requires much caution in using, as fully described by us in our answer to Query 520 in our issue of December 31st last, which should be referred to. There are now many disinfectants manufactured which are equally as effective as that named by our correspondents, and which may be used with less danger than corrosive sublimate, such as St. Bede's disinfectant, which is a convenient preparation containing corrosive sublimate, and Kuhn's, Fleming's, and Griffiths' disinfectants, as advertised in the colums of this journal.

986. — Written Complaint as to Defective Drains, &c.: Who may Make. — "Constant Subscriber" writes:—"I should be glad to know if in your opinion a Sanitary Inspector or Medical Officer of Health are competent persons to make a written complaint to the Local Authority under Sec. 41 of the Public Health Act, 1875. The section reads 'any person.' Of course the Inspector and myself are included in that, but further on the Inspector is to be empowered to do various things. I shall be glad to know your opinion on this matter. Of course, I am referring to cases which come to the knowledge of the Inspector and myself in our official capacities, and not in any way where we are concerned as private individuals."

Answer.—We known of no decision on the point, but incline to the opinion that either the Inspector of Nuisances or Medical Officer of Health may furnish the written application to the Local Authority under the provisions of the section referred to. Inasmuch, however, as there will, we anticipate, rarely be any difficulty in securing a written application from a private person, we should advise that this be done whenever practicable.

Contracts Open.

The dates given below are the latest up to which tenders can be received.

Brandon (Durham).—March 5th.—Scavenging.—Mr. Richard Gardner, surveyor and inspector, Langley Moor, near Durham.

Omagh.—March 5th.—Sanitary Works.—Mr. William Cathcart, clerk, Poor Law Office, Omagh.

Abram (near Wigan).—March 7th.—Removal of Nightsoil.—The Sanitary Inspector's Office.

Dewsbury.—March 7th.—Disinfectants.—Mr. G. Trevelyan Lee, town clerk, Town Hall, Dewsbury.

Felling (Durham).—March 7th.—Scavening.—Mr. H. Miller, Wesley-terrace, Felling.

Heswall-cum Oldfield (Cheshire).—March 7th.—Sewer, &c.—Mr. A. Hughes, surveyor, 24, Egerton-road, New Ferry.

Handsworth (Staffs).—March 7th.—Scavenging.—Mr. E. Kenworthy, surveyor, Council House, Handsworth.

Rochford. — March 7th. — Disinfectants. — Mr. Frederic Gregson, clerk, Southend-on-Sea.

Upton (Cheshire).—March 7th.—Sewers, &c.—The Surveyor's Office, 24, Egerton-road, New Ferry.

Bedlington. — March 8th. — Sewer, &c. — Mr. Cuthbert Brown's Office, Bedlington.

Tonyrefail (Llantrisant).—March 8th.—Sewers, &c.—Mr. Gomer S. Morgan, surveyor, Pontyclun.

North Shields.—March 9th.—Scavenging.—Mr. Augustus Whitehorn, clerk, 60, Saville street, North Shields.

Sandiacre (Derby).—March 11th.—Scavenging.—Mr. J. W. Newbold, clerk, Becket-street, Derby.

Broadstairs.—March 12th.—Sewerage Works.—Messrs. Henry Law and Son, 17, Victoria-street, Westminster, S.W.

Vacancies.

ASSISTANT SURVEYOR (LONDON, W., March 7th).—For the Vestry of St. Marylebone. Salary, £250 per annum. Vestry Clerk, Court House, Marylebone-lane, Oxford-street West.

CLERK OF WORKS (CARLISLE).—For the Corporation. Mr. Henry C. Marks, A.M.I.C.E., city engineer and surveyor, 36, Fisher-street, Carlisle.

CLERK OF WORKS (NEATH, March 28th).—For the Neath School Board. Salary £2 2s. per week. Mr. J. Cook Rees, architect, Neath.

ENGINEER (BIRMINGHAM, March 9th).—For the Public Work Committee. Salary £300 per annum, rising by increments of £25 per annum to £350 per annum. Mr. John Price, city surveyor, Council House, Birmingham.

INSPECTOR OF NUISANCES (CARMARTHEN, March 7th).—Salary £80. Town clerk, Carmarthen.

INSPECTOR OF NUISANCES, &C. (CASTLE BROMWICH, March 12th).—For the Rural District Council. Application forms to be obtained at the office of Mr. John North, clerk, 205, Vauxhall road, Birmingham.

INSPECTOR OF NUISANCES (RAUNDS, NORTHANTS, March 5th).—For the Urban District Council. Salary £50 per annum. Mr. W. F. Corby, clerk, Grove-street, Raunds.

SURVEYOR (LONDON, W., March 7th).—For the Vestry of St. Marylebone. Salary, £600 per annum. Vestry Clerk, Court House, Marylebone-lane, Oxford-street West.

WATERWORKS MANAGER (FAVERSHAM, March 16th).—For the Faversham Water Company, Ltd. Salary, £80 per annum. The Secretary's Office, 50, Preston-street, Faversham.

COMPETITIONS.

WINCHESTER, March 31st.—Public Baths. Extension of Time.—The time for submitting plans for the public baths competition is extended to March 31st. Premiums of £25 and £15 will be awarded for the designs adjudged by the Council of sufficient merit, and placed first and second in order respectively. The premiated plans will become the property of the Corporation. Drawings and detailed estimate to be deposited at the office of Mr. Walter Bailey, town clerk, Guildhall, Winchester, marked "Swimming Baths," on or before March 31st, instead of 28th inst., as previously mentioned.

To Surveyors, Sanitary Inspectors, &c.—First-class Cycles at reasonable prices. Don't place your orders elsewhere until you have seen our post-free catalogue.—MELROSE CYCLE COMPANY, Coventry.

INSURANCE.

SCHERING'S NEW DIETETIC.

This is a new albumen preparation for domestic use. Its constituents, similar to milk, especially Human Milk, give it a peculiar value.

SANOSE

SANOSE is an odourless and tasteless white powder, forming an emulsion when stirred in water.
THE MEDICAL PROFESSION strongly recommends it in cases of Anæmia, Dyspeptic troubles, Consumption, and in Cachectic Women.

For literature see "THE THERAPIST," November, 1897, and January, 1898.

Price 1s. per ounce; 3s. 6d. per 4 ounces.

Apply to all Chemists and Druggists, or to **A. & M. ZIMMERMANN**, 9-10, St. Mary-at-Hill, London. E.C.

NEW EDITIONS. JUST PUBLISHED.

FIFTH EDITION with numerous Illustrations, Crown 8vo., 10s. 6d.

HYGIENE AND PUBLIC HEALTH.

By LOUIS C. PARKES, M.D., D.P.H., Lond. Univ.,

Fellow of the Sanitary Institute; Lecturer on Public Health at St. George's Hospital Medical School; Medical Officer of Health for Chelsea

"Dr. Louis Parkes inherits a name which will ensure for him a ready hearing on matters relating to Hygiene and Public Health."—*The Lancet.*

"Eminently deserving of acceptance as a sound and trustworthy guide."—*Practitioner.*

"A text-book available not only for the requirements of the medical student, but also for candidates for the Public Health service."—*Edinburgh Medical Journal.*

SECOND EDITION, thoroughly revised, with numerous Illustrations, Crown 8vo, 5s.

THE SANITARY INSPECTOR'S HANDBOOK.

By ALBERT TAYLOR, Assoc. San. Inst.

Holder of the Inspector of Nuisances Certificate of the Sanitary Institute; Demonstrator to the Students of the Sanitary Institute; Chief Sanitary Inspector to the Vestry of St. George, Hanover-square, London.

"The book is admirably fitted as a guide to the Sanitary Inspector."—*The Sanitary Journal.*

"The author has managed to give as much useful practical information to the Sanitary Inspector as is possible within the limits of his book."—*Sanitary Record.*

LONDON: H. K. LEWIS, 136, GOWER STREET, W.C.

SANITARY INSTITUTE EXAMINATIONS.

TUITION BY CORRESPONDENCE.

An Engineer and Surveyor (Mem. San. Inst.), Certificated Surveyor and Inspector, prepares students for these Exams. by Correspondence through the post.

Fees strictly moderate. Cramming studiously avoided.

The course of tuition is arranged so as not only to qualify the student for passing the exams., but what is of equal importance, viz., that he may become a thoroughly efficient Inspector.

On successfully passing the exams., all possible assistance and advice is given to help forward intending candidates for public offices.

Many of my old pupils are now filling positions with salaries of over £120 a year.

For terms, &c., address "C. E.," care SANITARY RECORD, 5, Fetter-lane, London, E.C.

OFFICIAL ADVERTISEMENT.

REFUSE DESTRUCTOR.

THE URBAN DISTRICT COUNCIL OF Morecambe invite TENDERS for the CONSTRUCTION of a FOUR-CELL REFUSE DESTRUCTOR, including Boiler, Mortar Mill, ang Suitable Buildings, to be erected in Acre Moss Fieldd Morecambe, adjoining the Electric Light Generatin, Station.

Further particulars can be obtained by applying to the Council's Surveyor, to whom sealed Tenders, endorsed "Tender for Refuse Destructor," must be sent not later than 9 a.m. on Monday, the 7th day of March next.

The Council do not bind themselves to accept the lowest or any Tender, nor will they allow anything for Tendering.

By Order,
JNO. BOND,
Surveyor to the Council.

Council Offices, Morecambe,
22nd February, 1898

SANITARY ASSOCIATION OF SCOTLAND.

EXAMINATIONS IN SANITARY SCIENCE.

Examinations for Certificates of Competency in Sanitary Science are held each year as follows, viz.:—In Glasgow in April, in Edinburgh in October, and at such other time and place as the Board of Examiners may determine.

Entrance Fee £2 2s.

For further particulars apply to

GEORGE MIDDLETON, M.A., LL.B.,
Writer, 92, Bath Street, Glasgow,
Secretary to the Board of Examiners.

A Stamped Addressed Envelope must accompany all letters requiring an answer.

SANITARY INSTITUTE EXAMINATIONS.

SPECIAL Corresponding Classes for the **Practical Sanitary Science,** and **Sanitary Inspectors' Examinations** of the **Sanitary Institute, 1897,** conducted by a gentleman holding appointments as Urban District Council Engineer and Sanitary Inspector, holder of three certificates from the Sanitary Institute, First-class Honour Medallist Hygiene, &c. Hundreds of successes.—For all particulars, testimonials, &c., apply Mem. San. Inst., Office of THE SANITARY RECORD, 5, Fetter-lane, London E C.

STRICTLY MEDICAL

DR TIBBLES' Vi-Cocoa

DR TIBBLES' Vi-Cocoa

DR TIBBLES' Vi-Cocoa

DR TIBBLES' Vi-Cocoa

DR TIBBLES' Vi-Cocoa

DR TIBBLES' Vi-Cocoa

The "LANCET" says:

"Vi-Cocoa must be assigned a place in the front ranks of really valuable foods, since it is the embodiment of all the numerous principles contained in Malt, Hops, Kola and Cocoa . . . of distinct value as a restorative and stimulative food."

The "BRITISH MEDICAL JOURNAL" says:

"Vi-Cocoa is a very palatable beverage of great stimulating and sustaining properties."

The "MEDICAL MAGAZINE" says:

"Medical practitioners will find a valuable weapon in Dr. Tibbles' Vi-Cocoa in combating the various conditions of nervous exhaustion and enfeebled digestion. The ingredients of which it is composed are carefully selected, and of undoubted strength and purity."

The "POPULAR MEDICAL JOURNAL" says:

Dr. Tibbles' Vi-Cocoa is an excellent combination of Kola and Cocoa; and it not only gives the nutritious and sustaining properties, but, having Hops incorporated with it, acts as a tonic and is soothing, while the addition of Malt neutralises all the starchy matter, and so considerably assists weak digestions."

From EDMUND A. ELLIOTT, M.R.C.S., L.R.C.P.

"I have tried Dr. Tibbles' Vi-Cocoa, and my patients are very pleased with it."

From Dr. T. H. SMITH, Royal Colonial Institute, Northumberland Avenue, W.C.

"I have much pleasure in testifying to the superior qualities of your Vi-Cocoa over any similar preparation in the market. I do this willingly and unsolicited, as I consider it a great boon to the public. I have personally experimented with the cocoas in the market, and find that the great drawback to all of them was the slow process of digestion and assimilation. The diastase in the Malt not only assists digestion in your Vi-Cocoa, but it also accelerates the digestion of other foods that are taken with the Vi-Cocoa. This I have personally tested, and can therefore speak from actual experience. Its wonderful recuperative power after exhaustion from fatigue is marvellous."

Merit, and merit alone, is what is claimed for Dr. Tibbles' Vi-Cocoa, and the proprietors are prepared to send to any reader who names this paper (a postcard will do) a dainty sample tin of Dr. Tibbles' Vi-Cocoa free and post paid.

Dr. Tibbles' Vi-Cocoa, 6d., 9d. and 1s. 6d. Can be obtained from all Grocers, Chemists, and Stores, or from Dr. Tibbles' Vi-Cocoa (Limited), 60, 61 and 62, Bunhill Row, London, E.C.

IMPORTANT ANNOUNCEMENTS.

WILL SHORTLY APPEAR IN THE

Sanitary Record

A SERIES OF ARTICLES

ENTITLED—

"THE CHEMICAL AND BIOLOGICAL EXAMINATION OF WATER,"

BY

C. G. MOOR, M.A., F.C.S.

These Articles, which have been expecially written for THE SANITARY RECORD by Mr. Moor, will be fully illustrated, and will embody the results of the latest researches on this all-important subject.

The writer holds a unique reputation as joint author (with Mr. T. H. Pearmain) of "Applied Bacteriology" and "Aids to the Study of Bacteriology," both of which works have received high encomiums from the *Lancet*, the *British Medical Journal*, the *Chemical News*, &c., and we have no hesitation in commending this new series to the notice of all Public Bodies who are interested in the purity of public water supplies.

A

New Series of Articles

BY

W. J. DIBDIN, F.I.C., F.C.S.,

Late Chemist to the London County Council, Author of "The Purification of Sewage and Water," &c.,

WILL COMMENCE IN

The Sanitary Record

AT AN EARLY DATE.

Mr. Dibdin has chosen for his subject—

"LIME MORTAR AND CEMENT: Their Composition and Analysis,"

And the Articles will prove invaluable to Surveyors, Municipal Engineers, &c.

The date of publication will be duly announced in this column.

NOTICES.

ANNUAL SUBSCRIPTIONS.—The Annual Subscription to "The Sanitary Record," paid in advance, is 10s. *This includes postage, and a Copy of the Diary, post free.*

SUBSCRIBERS RESIDING in SCOTLAND and IRELAND are requested to pay by P.O. and NOT *by cheque. If cheques* BE *sent they must be drawn for* 10s. 6d

MSS. cannot be returned unless accompanied by a stamped directed envelope.

Advertisements cannot be inserted unless received before Four o'clock on the TUESDAY of each week.

All communications should be addressed to the EDITOR, at 5, *FETTER LANE, London, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, Ld.*

THE

Sanitary Record,

MARCH 11, 1898.

Notes.

The County Council Elections.

THE elections for the County Council of London have resulted in a substantial victory for the Progressives, who have secured sixty-eight seats as against forty-eight seats held by the Moderates. This represents a net gain for the Progressives of twelve seats.

The results for Central Hackney, which is at present represented by two Progressives, have still to be declared; and on the assumption that there will be no change in this constituency, the total majority of the Progressives in the new Council will be twenty-two—a very decided majority, which will give them every opportunity they could wish to unfold their policy according to their desires. The elections have undoubtedly been fought on strictly party lines, and it now remains to be seen whether, in shaping the future policy of the Council, the majority will give it a party character. It is undeniable that there will be a strong temptation to do so; but it is sincerely to be hoped, in the interests of the municipal government of London, that party politics will not be carried into the Council Chamber. What effect the Progressive victory will have on the Government's promised Bill, dealing with the government of London, is not yet known; but it is stated that the Bill will be proceeded with in accordance with the original intention, though it is possible that its character may now be subject to some modification.

The London University Bill.

While London is still in the throes over the problems of municipal government, it is satisfactory to know that the question of its higher education is now in a fair way to be settled. On Friday last the House of Lords passed the second reading of the Bill which is intended to establish a Teaching University for London. The measure is substantially the same which passed through the Upper House last year, but it has been modified in various particulars in order to conciliate the opposition which it then met with—opposition which the Duke of Devonshire said was principally based on certain unfounded apprehensions that the high standard of the London degree would be lowered. As the Bill has the almost unanimous support of the teaching institutions of London, and is backed by an overwhelming body of scientific opinion, it is hoped that it will become law this session. So far from its tending to depreciate the standard of the London degree, it seeks to enhance its value, and to this end it is necessary, as Lord Reay said, to increase the opportunities for scientific work, and to give the students more scope for individual research and originality than they at present possess.

Factory Act questions in Parliament.

On the Vote on Account for the Civil Service and Revenue Departments last week an interesting debate took place with regard to the exemption of fish-curing from the operation of the Factory Acts, the prevention of lead poisoning in potteries, and the position and duties of female Factory Inspectors. The Home Secretary acknowledged the importance of the various questions raised. He admitted that the law in regard to the fish-curing industry was not in a satisfactory state, and promised to consider the means of diminishing the existing exemptions, which were undoubtedly at present too wide, without an undue disturbance of the trade. With regard to female Inspectors, or what was called the Women's Department of the Home-office, several points were raised in connection with their status and powers, but the prevailing note of the discussion was one of commendation and praise of the efficiency with which they discharged their duties. Mr. Asquith pointed out that this was especially gratifying when one remembered the doubt that was at first entertained of the policy of appointing women for the inspection of factories and workshops. The success of this policy is now acknowledged to be such that no one at the Home-office would think of endeavouring to carry out the work of the Department without a large infusion of the female element.

Lead Poisoning in Potteries.

The danger to health in the case of women and young persons engaged in potteries where lead is necessary for glazing and other processes in the manufacture, was emphasised by all the speakers, and the Home Secretary admitted that the special rules made in 1893 were not adequate for their protection. Various specific remedies were suggested in the course of the debate. Sir Charles Dilke considered that the susceptibility of women and children to lead poisoning was such as to justify the total prohibition of their employment in the industry. Sir Matthew Ridley thought that an attempt might be made by the Home-office to co-operate with manufacturers in endeavouring to discover a less unhealthy ingredient to be used in potteries than poisonous lead; and Mr. Asquith desiderated some beneficent invention—some mode of respirator—so contrived as to prevent the inhalation of noxious gas or dust without causing discomfort to the wearer. Another point in regard to which the existing law is felt to be unsatisfactory is that, under the definition of "accidents" in the Compensation Act of last year, it is impossible for a person to obtain compensation for even permanent injury to health on account of the dangerous atmosphere of the workshop arising from the material used in the ordinary course of manufacture.

The Small-Pox at Middlesbrough.

It is satisfactory to learn that the outbreak of small-pox at Middlesbrough shows signs of diminution, and that the claim of the Authorities that they have now got the upper hand of the epidemic appears to be justified. The number of cases notified last Friday was only twenty-four, as contrasted with sixty-five notified one day earlier in the week; of these, however, it is to be observed that twenty-one were from houses previously free from the disease. The total number of cases recorded since the commencement of the outbreak, up to Friday, was 810. The temporary hospitals are now in thorough working order. There are 585 available beds in the buildings already completed, and when the third section of the hospitals is finished, there will be other 300 beds provided. On account of the danger of the spread of the disease by clergymen visiting the patients, the Sanatorium Committee have decided not to allow clergymen to visit the hospitals, unless they agree to submit themselves to be disinfected to the satisfaction of the doctor. The Local Government Board have intimated that, considering the proportions that the epidemic has attained, they are prepared, if requested, to send down a special

medical man to assist in dealing with the cases. If, however, the present hopes of the Authorities are fulfilled, perhaps it will not be necessary for them to avail themselves of this offer of assistance.

Adulteration of Dairy Produce: The Foreign Trade.

Mr. Balfour's assurance to the deputation of Unionist members for agricultural constituencies that the Government hope to find a favourable opportunity to bring forward legislation regarding the adulteration of dairy produce, though a little vague, awakens the hope that the subject will soon be dealt with and placed on a satisfactory footing. As things are at present there is no doubt that foreign adulteration is largely responsible for the falling off of British trade in these commodities, and it must at the same time be admitted that the shortsighted policy of many British farmers is a not unimportant factor in the situation. It has been stated that in 1876—78 the proportion of imported dairy produce to the home production was 36·3 per cent., and in 1893—95 it had reached the high figure of 51·3 per cent. At the present time it is believed that the proportion is still larger, and that the amount of foreign butter and cheese in our markets is considerably in excess of the home production of these articles. Now a great deal of the butter imported to this country is "blended." About 150,000 cwt. of the Danish butter we receive every year is imported from Sweden, blended, and then re-exported here. So too, in France and Germany, Normandy in particular being considered a peculiar adept in this form of adulteration; the native butter is adulterated with various imports, and the blend is then shipped to the British Isles.

Defects of the Home Produce.

These facts show the necessity for legislation on the subject so far as foreign produce is concerned. The importation of foreign butter, however, be it ure or adulterated, would not have been so great were it not that even the blend is often better as well as, cheaper than the average English article. The best British butter is unsurpassed, but much of what is on the market is of very inferior quality. In Ireland, moreover, it is stated that home butter suffers much by comparison with Danish in point of general cleanliness and appearance. Probably, also, the mode of shipment has to be considered, for the experience of Canada has been that both the quality and the flavour of their butter placed on the English market has undergone a great improvement since the utilisation of the cold storage accommodation on board ship. There are supplementary considerations to be kept in view by those who wish to see British dairy produce raised to the position that it ought to hold, but the really essential point is that a good, wholesome, and uniform standard for milk should be established. The varying standards that are at present in vogue are most unsatisfactory. We see that Mr. Carrington Smith, lecturing to the London Farmers' Club, advocated a standard of not less than 3 per cent., or even 3·25 per cent., of butter fat, a standard which is certainly considerably higher than what is generally insisted on; but it is good to have a high deal.

Model Regulations for Cowsheds.

A suggestion has recently been made that it would be of great service to Local Authorities and dairy farmers in determining the requisite air space and other sanitary conditions for cowsheds, if the Local Government Board were to construct a model byre, and by actual experiment ascertain approximately how much ventilation is essential for the health of the cows and the safety of the public. Hitherto the Local Government Board have fought rather shy of the question. According to the existing law, Local Authorities are empowered to make such regulations as they deem necessary, subject to the veto of the Local Government Board, a veto which is rarely exercised. The result is that the regulations issued by Urban and Rural District Councils vary widely—"model regulations" they are called—and the issue of some of these model regulations, requiring the provision of from 800 to 880 cubic feet of air space per cow, has excited a good deal of alarm among dairy farmers, on account of the impossibility of conforming with them without a very serious expenditure. The farmers growl, for they say they are already sufficiently overburdened, and from one quarter we have even heard the suggestion of a farmer's strike!—which, however, we do not suppose is to be seriously treated.

The Difficulty of a Standard.

In some respects it must be admitted that there is some cause for these complaints. Cowsheds are not all alike; the greatest differences are to be found both in construction and situation. These are factors which have almost as important a bearing as cubic capacity on the question of ventilation, and probably due allowance is not always made for their influence. It is impossible to expect that a definite standard can ever be attained; the most that we can look for is an approximation. But with the admitted difficulty of satisfying everybody, and the hardship that is involved in many cases by a lack of uniformity, we think it is eminently desirable that so important a matter should not be left entirely to the discretion of the Local Authorities. The suggestion has often been made that the Local Government Board should issue forms of model regulations for the use of District Councils, which would insure some measure of uniformity; and it is probable that this may be done after the issue of the report of the Royal Commission on Tuberculosis, in which the question of air space in cowsheds is certain to be treated.

Honour to a Statistician.

An interesting ceremony took place at Marlborough House the other day, when the Prince of Wales, as President of the Society of Arts, in presence of a distinguished gathering of scientific men, presented the Albert Medal to Mr. George James Symons, F.R.S. The honour was conferred in recognition of the valuable services Mr. Symons has rendered to sanitary engineers, and to the country at large during the past forty years, by his systematic observations of the rainfall of the British Isles. The system has been gradually built up and

matured, and the observations are now carried on at over 3000 stations. The results are carefully recorded and tabulated, and graphically set forth in Mr. Symons' annual publications. The honour accorded by the Council of the Society of Arts is well merited.

Statistics the Foundation of Sanitary Science.

The value of statistics to sanitary science was emphasised by Sir William Gairdner in his lecture which we reported last week. He there pointed out that sanitation as a moderately exact science could not be said to exist until the establishment of death and disease rates, for the purpose of studying the incidence of particular diseases in different localities, and under various conditions of life. Prior to this epoch, much valuable work had been done by the early sanitary reformers, such as Sir Edwin Chadwick, Lord Playfair, Dr. Southwood Smith, and others, to whom all honour is due on account of their pioneering efforts; but their methods were not scientific, and until the establishment of a scientific method little real progress was possible. Progress, however, can be distinctly traced from the time of the application of the methods of science to the investigation of the incidence of disease. It was Dr. Farr, head of the office of statistics of the Registrar-General of England, who first conceived the idea of furnishing a calculus to ascertain this incidence by means of the death-rate, and it is upon the system that he founded that all modern sanitary science is based.

The Death-rate System.

Dr. Farr mapped all England out into districts for the purpose of estimating the number of deaths in proportion to the population of each district. In only three districts was the death-rate found to be so low as 15, in fourteen districts the rate was 16, and in forty-seven districts it was 17. The last-mentioned rate was accordingly selected as the standard. Now, to compare this initial standard with that now in operation, at once gives us a vivid idea of the results effected by hygiene. Dr. Tatham, the present head of the Statistical Department, while working on exactly the same lines as Dr. Farr, though with still greater precision, is now able to operate with a standard death-rate of 15 in the 1000, instead of 17; during the last decade one-sixth of the population of England in 263 districts had death-rates below 15 in the 1000, and fully a quarter of the population were below the ideal standard aimed at by Dr. Farr.

INSANITARY FLOORING IN PUBLIC AND PRIVATE BUILDINGS.

The results of some interesting researches showing the dangers from a sanitary standpoint of hollow floors, false ceilings, and of the joints and crevices which are so frequently found in building constructions, are embodied in a recent issue of a German contemporary, *Industrielles Echo*. The investigations were made by Dr. Emmerich, and extended over a large number of public and private buildings, his *modus operandi* being as follows:—In each room a series of samples of pugging were taken, such samples representing the full thickness of the pugging in each case. Every sample was separately and carefully tested as to its chemical composition and the amount of organic matter contained in it. This involved an immense amount of labour on account of the large number of the samples, and also entailed some amount of danger owing to the nature of the material dealt with. The result of the numerous tests goes to show that there is no soil so richly contaminated with decomposing organic matter as "pugging," which, during the entire time of their being in use—in some cases for more than a generation — receives all manner of organic particles, spores, and liquids which reach it through the cracks and joints of the flooring, thus forming a mass which, in some neighbourhoods—Rhenish Hessia, for instance—is used as manure whenever the floors are taken up. And for use as such it is eminently fitted on account of the very large proportion of putrescent organic matter it contains. In one instance it was ascertained that in a quantity of such old pugging the fermentation of the numerous fungoids it contained carried the temperature to 32 deg. Cent. in the shade, the temperature in the air being only 16 deg. This defect is accentuated by the circumstance that it is the almost universal custom to use dry rubbish from old buildings for such pugging, that being generally the driest material obtainable, so that all manner of ferments and bacteria derived from those ancient times when epidemics were most rife are brought into the modern dwelling.

Dr. Emmerich found such pugging fouled to an enormous extent by fæces and other putrescent matter, such as rags, straw, paper, potato peal, vegetable offal, hair, bones, sweepings, &c. In one new building these nursery grounds for bacteria amounted to 27,158 kilos. of dry albumen (calculating the same from the proportion of nitrogen). Now a human body contains about 9 kilos. of albumen, so that the rotting mass in this one building alone was equivalent to 3000 corpses rotting under the floor, the smell being masked solely by the deodorising effects of the earth and ashes mingled therewith.

Dr. Emmerich concludes his report as follows:—"It is small wonder, then, that local epidemics occur even in the cleanest new houses." Even if the best material is used as pugging, an ancient abuse of the workpeople employed in the building leads to its contamination, and this explains why epidemics start just from one or two corners of a given room. On examination of a certain sample, the medical men testing it were invariably made sick when dealing with it. Owing to more strict supervision by the Sanitary Authorities, who cannot possibly be too rigorous in matters touching the public health, old rubbish is now-a-days less frequently used as pugging, sand and ashes being more usually employed; yet in many instances gross faults could be cited, and many a new smart-looking residence contains breeding grounds for vermin and the more insidious bacteria below its floors.

Builders and owners would, we think, do well to ponder over these facts, both in connection with the construction of flooring in new buildings, and in the reconstruction of old ones, and make it their duty to see that filth is not introduced to the detriment of the same by workmen.

NOTES ON
PRACTICAL SANITARY SCIENCE.

By WILLIAM H. MAXWELL.

Assistant Engineer and Surveyor, Leyton Urban District Council, Author of "Drainage Work and Sanitary Fittings," "Ventilation, Heating, and Lighting," &c., Certificates of the Association of Municipal and County Engineers, and Sanitary Institute.

No. 52.—REFUSE DESTRUCTORS.

(*Continued from page* 223.)

Beaman and Deas Destructor.

One of the most modern destructors is that of Messrs. Beaman and Deas[133], which is illustrated in plan and section by the accompanying figures (20 and 21), which show the general arrangement and construction of the furnace. The Beaman and Deas destructor is, at the present time, commanding a large share of attention from Public Authorities throughout the United Kingdom, and installations have already been erected at Warrington, Dewsbury, Leyton, &c., whilst Barry, Bermondsey, Burnley, Colne, Nelson, St. Helens, Stretford, Streatham, and Rotherhithe, are either erecting, or have decided upon the erection of this type of furnace.

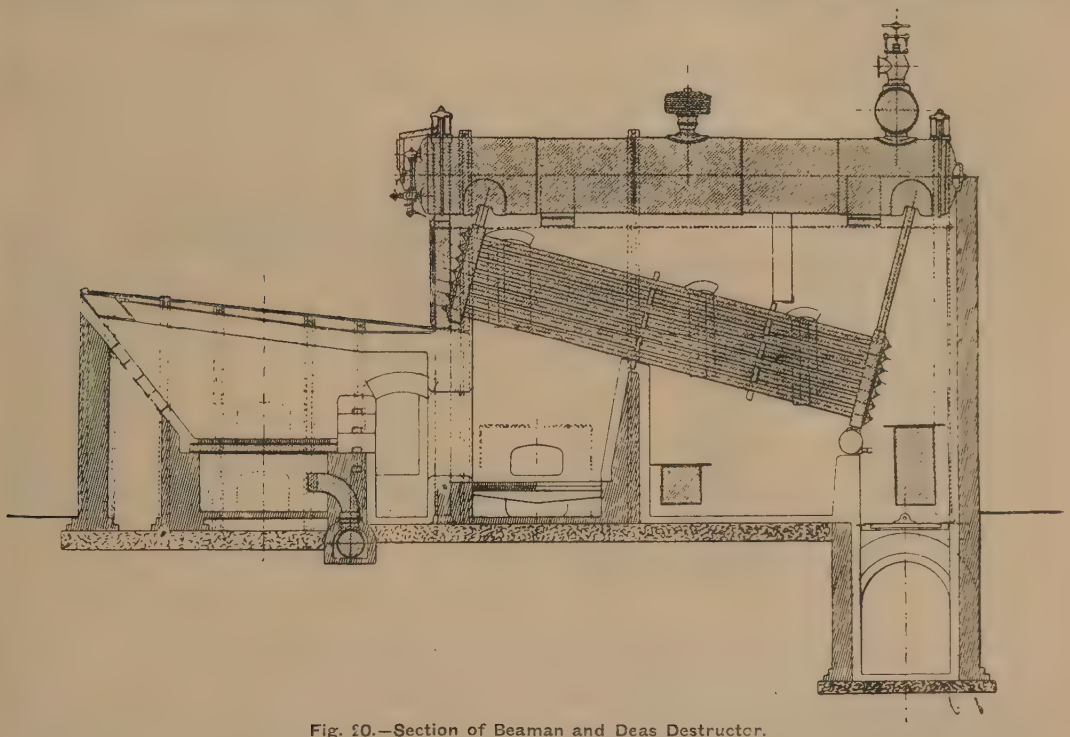

Fig. 20.—Section of Beaman and Deas Destructor.

The material to be burnt is carted up a short incline to the top of a platform, which measures only 8ft. 9in. from the ground level, and is tipped direct into a hopper mouth about 1ft. 6in. square; after passing which it falls down a fire-brick hearth supported on T irons, as shown, and having an inclination with a horizontal line of about 52 deg. At the bottom of this incline the refuse is received upon a fire-grate area 5ft. square, which is fixed level at a height of about 2ft. 9in. above the floor of the ashpit. The fire-bars are of the ordinary stationary type, these having been found by experience to give the most satisfactory results. They have spaces between them of only $\frac{3}{32}$in., and the weight of fine ash passing through from a week's work of five days—and burning about 100 tons—only amounts to 3½ cwt. Vertically under the bridge between the furnace and the combustion chamber is an air culvert, on the top of which are the air blast pipes, about 12in. in diam., and which discharge into a hermetically-closed ashpit immediately under the fire-bars. The air is supplied from fans at a pressure of about 2in. of water, and is controlled by means of baffle valves worked by handles on either side of the furnace, handy to the attendant. The forced draught keeps the bars cool, and the wear and tear is found by experience to be very slight.

The fumes from the charge drying on the hearth pass through the fire, directly over the fire-bars and over the fire-bridge. The bridge is perforated longitudinally with air passages, as shown in the figure; these perforations connect with a miniature flue, leading from a grated opening on the face of the brickwork outside. This creates a strong draught, and the air in the course of its passage becomes heated, is discharged near the top of the bridge, and thus meets the fumes passing over into the combustion chamber, and ensures their perfect combustion by means of this auxiliary supply of heated oxygen; the principle of the action being, in fact, somewhat similar to that of the Bunsen burner. The combustion chamber, which attains

[133] Patents No. 15,598 (1893) and 23,712 (1893).

an exceptionally high temperature, is provided with large iron doors at each end, for the admission of infected or other articles, and also for access for the periodical removal of fine ash from the flues.

The Beaman and Deas furnace being a good steam or power producer, a boiler to each pair of cells may be advantageously fixed in combination therewith for the supply of power for any purpose for which it may be required, such, for example, as the driving of fans, lifts, pumping, or other machinery, or for generating electricity. The boiler shown in the illustration is a water-tube boiler of the Babcock and Wilcox type, and is heated by the gases from the combustion chamber which pass, on their way to the main flue, three times between the boiler tubes. A secondary furnace is shown under the boiler for raising steam when the cells are out of use.

The original points claimed by the patentees for their invention are, briefly: a destructor furnace consisting essentially of a flat or inclined furnace grate, an inclined feeding hearth, a reverberatory arch extending over the grate and hearth, a vertical perforator fire-brick screen, a fire-bridge, and a chamber formed between the screen and the bridge.[134]

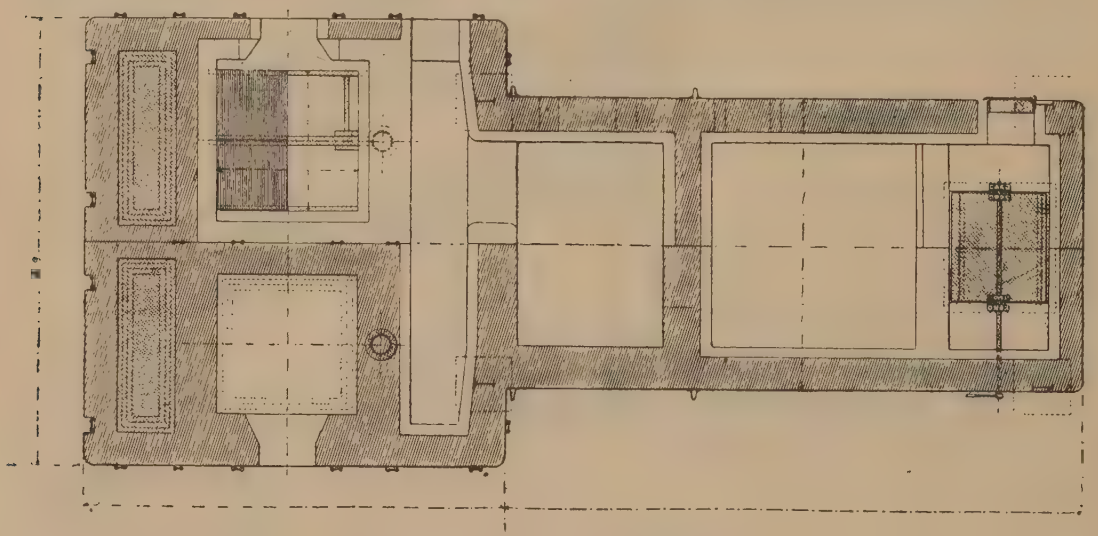

Fig. 21.—Plan of Beaman and Deas Destructor.

The process of burning the refuse is, briefly, as follows:—The material to be consumed is carted to the tipping platform, and, without undergoing any process of screening or selection, is discharged through the hopper, as above referred to, on to the inclined hearth. A charge is meanwhile in course of destruction on the horizontal fire-grate, and when this is consumed the furnace is clinkered, and the charge lying on the inclined hearth, which has meanwhile, to a considerable extent, been dried by the heat deflected from the fire-brick hearth and the general heat of the furnace, is in turn drawn on to the horizontal fire-grate, and another charge takes its place on the inclined hearth. The clinkering and re-charging of the furnace is done alternately, the better to preserve the heat in the combustion chamber, which is stated to be maintained at a temperature of 2000 deg. Fah. Inasmuch as all the products of combustion have to pass through this chamber it is impossible for any undecomposed vapours to escape into the main flue beyond, and one of the most important of all questions appertaining to the disposal of refuse, viz., the absolute avoidance of nuisance, is thus provided for.

In relation to the efficiency of the working of the Beaman and Deas furnace, Mr. C. Estcourt, F.I.C., Analyst to the City of Manchester, has made the following observations in his report on the destructor at the Longford depôt of the Warrington Corporation:—"In the first place, I may state that in my opinion (grounded upon the observations I have made) the use of this destructor does not cause the slightest offence or nuisance; secondly, that the refuse dealt with is reduced to a very small quantity of clinker, containing no organic matter. I took particular notice of the chimney shaft, and I may say at no time did I see any charred paper or any other dust coming from it. . . . From my examination of the gases coming from the chimney shaft, I am quite sure that they are perfectly innocuous, and free from anything harmful. No organic or mephitic vapour can escape even into the flue during the process of combustion in this destructor.

"I have made analyses of the gas drawn from the chamber in the flue, under all the three main conditions of working, *i.e.*, (1) immediately before clinkering; (2) during clinkering; (3) immediately after clinkering, when the new charge of refuse had been drawn into this destructor, and I can state that I did not find any harmful gas escaping from these furnaces.

"I found no trace of sulphuretted hydrogen. There is no trace of carbonic oxide, showing that practically *perfect combustion* is attained by this destructor.

"I observed, also, that during the process of burning the silicious particles, &c., appear to be carried in a fused condition up to the arch of the

[134] Patent No. 23,713 (1893).

furnace, and attach themselves to the brickwork, thus *forming a complete protection to the furnace*, and obviating the danger to which many destructors are subject, of being burnt out. I was shown a brick from the arch, which had been in fourteen months, and which gave no sign of wear.

In regard to the formation of these stalactites upon the roof of the furnace, Mr. J. Carter Bell, F.I.C., of Manchester, observes, in a report on the Warrington Destructor,[135] that objections may be taken to the great heat generated on the grounds of its being likely to destroy the lining of the furnace; but, as a matter of fact, "this great heat is an immense advantage, for through the blast which is blown in a fine spray or shower of clinkers is formed, which fixes itself upon the roof and exposed portions of the furnace in a stalactitic form, thus protecting the brick lining from the intense heat. Some of these stalactites were knocked off in my presence, which I have analysed, and the following is the analysis :—

Silica	55·364
Oxides of iron	15·711
Alumina	17·362
Lime	5·390
Magnesia, potash, soda, sulphuric acid ...	6·173
	100,000

"This furnace has been at work since August, 1893, and is as good now as the day it was erected. I consider the furnace to be a perfect destructor, and very much superior to any others I have seen."

Another very important point has been pointed out by Mr. C. Estcourt, viz., that pieces of paper and other light material lying in any part of the furnace, even directly over the blast, retain their position until consumed. One serious source of nuisance common to other forms of destructor is thus avoided, namely, the emanation from the chimney shaft of pieces of charred paper, &c.; also the fumes from the fresh charge, lying upon the hearth, pass through the fire directly over the fire-bars.

In March, 1896, a series of tests on the Beaman and Deas furnace at Warrington were made by Mr. F. F. Bennett, M.I.E.E., of Preston, for the purposes of his report to the Electric Lighting Committee of the Radcliffe Urban District Council, who have had the question of a joint destructor and electric lighting scheme under their consideration. During a *six-hour* test it appears that 9 tons 13 cwt. 3 qr. of Radcliffe town refuse were consumed. The average of thirteen readings during the test gives the following results :—

Steam pressure	45 lb. per square inch.
Temperature of feed-water...	141·5 deg. Fah.
Temperature of *flue* gases ...	519 deg. Fah.
Draught in *flue*	½in. (water gauge).
Draught in *ashpit*	2·5in. (water gauge).

Each furnace was charged once every half-hour—a charge consisting of 16 cwt. 16 lb. of refuse. The weight of water evaporated was 22,000 lb., and therefore, for every 1 lb. of refuse destroyed, 1·11 lb. of water was evaporated. The material contained a considerable quantity of moisture, being 48·44 per cent. of the whole. Had the refuse contained no moisture, the amount of water evaporated would have been 1·98 lb. for every pound of dry refuse destroyed, so that the drier the refuse the better the result.

With a good compound condensing engine, requiring the evaporation of 20 lb. of water per indicated horse-power, the result of the test would have been a development of 1100 indicated horse-power, or 183 indicated horse-power per hour. Working on the basis of a former report, Mr. Bennett calculates that "this would supply sufficient energy for 3660 30-watt lamps per hour. In other words, with 10 tons of refuse, a pair of Beaman and Deas destructors, and one Babcock and Wilcox 200-horse power boiler, you would be able to run 3660 30-watt lamps for a period of six hours, and if the refuse is in a drier condition, a still better result would be obtained. With two pairs of destructors and two such boilers, with fan and pump, including delivery and erection, and costing about £3660, double this quantity of lamps could be supplied per day, requiring about 120 tons of refuse per week."

One pound of ordinary slack coal will evaporate from 4 lb. to 6 lb. of water; and 1 lb. of good coal from 8 lb. to 10 lb. of water. It may therefore be safely assumed that house refuse, for heating and evaporative purposes, is equal to 25 per cent. of the value of slack.

Huddersfield Corporation Test at Warrington.—As this Authority wished to ascertain what the Beaman and Deas furnace could accomplish with their refuse and sludge they sent to the Warrington destructor 4 tons 12 cwt. of *sludge*, which was mixed with 6 tons 12 cwt. of *refuse*—a proportion of not quite 1½ to 1—making a total of 11 tons 4 cwt. This was burnt in 5¾ hours, being at the rate of 24 tons 9 cwt. per cell per day of 24 hours. The residue of the whole amounted to 2 tons, or 17·85 per cent.

The amount of water evaporated on the occasion of this test was 32,000 lb., which equals 1·27 lb. of water per pound of refuse and sludge consumed, with the feed-water from and at 65 deg. Fah.

The sludge at Huddersfield is of a moist description, and the sample sent was thoroughly saturated by being exposed to heavy rain.

The test was carried out in the presence of two of the Huddersfield Corporation officials, namely, the Assistant Surveyor and the mechanical engineer.

The following are some of the chief results obtained at the Warrington installation in a twenty-four hour test made in November, 1893, by Mr. G. Darley, Superintendent Ashpit Cleansing Department, Leeds, and Mr. G. T. Carter, of the City Engineer's Office, Leeds :—

Nature of fuel	Unscreened refuse
Quantity of fuel per hour... ...	2231 lb.
Quantity of water per hour (evaporated)	2556 lb.
$= \frac{2556}{20} = 127$ I.H.P.	
Percentage of clinker	27·9
Pressure of steam maintained...	68 lb.
Temperature of air in boiler-house	45 deg. Fah.
Temperature of feed-water ...	104 deg. Fah.
Temperature of gases leaving damper	650 deg. Fah.
Quantity of water evaporated per pound of refuse...	1·14 lb.
Average temperature by copper wire test	2000 deg. Fah.
Average air pressure (water gauge) maintained	2½in.
Draught velocity in feet per minute	820.

Another test, of 5⅚ hours' duration, made on

[135] Report, June, 1894.

behalf of the Warrington Corporation in March, 1896, with a fair sample of Warrington refuse, gave the following results :—

Weight of refuse discharged on furnaces per hour	3173 lb.
Amount of moisture in refuse...	30 per cent.
Percentage of clinker...	15·4
Average steam pressure carried in boiler	53 lb.
Average temperature of feed-water	135 deg. Fah.
Weight of water evaporated per hour	4·766 lb.
Weight of water evaporated per pound of unscreened refuse ...	1·5 lb.
Weight of water evaporated per pound of unscreened refuse, assuming feed 212 deg.... ...	1·66 lb.
Water evaporated per pound of refuse, assuming it in dry state	2·1 lb.
Water evaporated per pound of refuse, assuming it in dry state and feed-water at 212 deg.	2·32 lb.
Temperature of flue gases ...	576 deg. Fah.
Draught in flue in inches of water	$\frac{9}{10}$in.
Draught in ashpit	2in.

(To be continued.)

THE SANITATION OF DOMESTIC BUILDINGS.

By Frank Latham, C.E., M. San. Inst., &c., Assistant Surveyor, Borough of Margate.

CHAPTER VI.

Section 1.

Internal Sanitary Fittings.

These fittings, which include water-closets, slop and other sinks, flushing cisterns, urinals, baths, and various other internal arrangements in connection with house drains, are matters on which much can be said, and mainly that the best appliances should be used, seeing that good

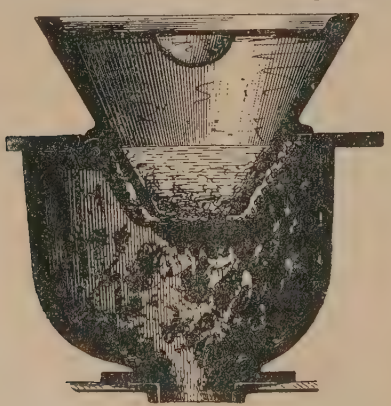

Fig. 51.

drainage is often tainted and rendered unwholesome by the use of unsuitable or inferior and unsanitary fittings. The principal of these fittings requiring attention is the water-closet apparatus, which is a trapped opening to the drains, and generally located within the dwelling; therefore should be perfect. The water-closet apparatus has taken many years to bring to its present state of cleanliness, and to ensure this condition the simpler its construction the easier it is to maintain in order. Much improvement has of late years taken place in this form of sanitary work, superseding to a great degree the old appliances.

It will be more convenient to divide the subject of water-closet construction into two sections :— Firstly, dealing with those forms of apparatus which, although insanitary and obsolete are still to be found in use (some of the better description of this class being still fixed by unscrupulous builders when opportunity occurs for so doing), and secondly, with the most suitable forms of apparatus.

By far the worst possible form of water-closet apparatus now found in use is the pan water-

Fig. 52

closet (Fig. 51). This apparatus is fitted with a copper pan having plenty of angles to hold filth, which, when the pan is not in a leaky condition, holds water in the basin. The pan upon being tipped discharges its contents into a receiver, and at the same time exposes the contents of the latter foul receptacle to the house. The receiver is a large iron receptacle, affording every facility for the deposit of sewage; this receiver generally discharges into the soil-pipe through a D trap, which is another highly-objectionable arrangement, the whole—or part, in most instances—being flushed through a fan spreader at the back. Altogether this apparatus is a combination of the most insanitary contrivances. Now-a-days, however, very few words are required in condemning this apparatus, and the Sanitary Inspector, should people insist on letting it remain, can require the occupier to occasionally remove the receiver for burning-out purposes, the annoyance and cost of doing this soon inducing the householder to get the closet replaced by a proper appliance. Furthermore, the model bye-laws of the Local Government Board prohibit its use in new buildings.

The old hopper water-closet (Fig. 52) is another insanitary contrivance. The main fault in this closet is the basin; it being conical in shape, the surfaces become filthy from top to bottom, and whether fitted with flushing rim and good flush or not it after a while becomes quite foul and objectionable. The plug or plunger closet (Fig. 53) consists of a basin, at the side of which is a chamber provided with a plug, fitting down into the mouth of the trap. This plug is intended to retain a body of water in the basin, and upon being lifted and the apparatus flushed, gives outlet to the contents of the closet. This apparatus is not a good one, there being a great deal of surface exposed to the air of the house when in action, and the plug chamber,

which is not easily accessible, becomes filthy, besides which the action of the plug is not to be relied upon, as it is very liable to lose the water flush from the leaky state of the plug, which is generally its normal condition.

The wash-out closet (Fig. 54*) is a more modern form of apparatus, the basin of which is made to retain water at the bottom by its being hollowed. The closet is not satisfactory, being rather odorous, owing to the soil not being properly immersed in water till reaching the trap, and upon

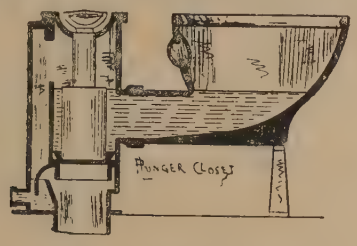

Fig. 53.

being flushed is broken up and dashed against the outlet and then into the trap, from whence it generally has a difficulty in clearing itself, and often remains there till again used.

It must not be taken for granted that a good-looking closet is a sign of its being sanitary, as some of the bad forms are well got up and highly ornamented, especially inside the basin, which is very seldom done in new forms, they being as a rule plain white.

The old custom of framed-in closets is a mistake, although some people, who have a fancy for their apparatus appearing like a piece of furniture, prefer them so done, the result being that a fœtid odour is inseparable from them. They are also frequently a screen for bad work. The author has on several occasions been called in to investigate cases of certain rooms in houses being unusually close and foul smelling, and has invariably had to attribute the cause to the use of framed-in closets, and

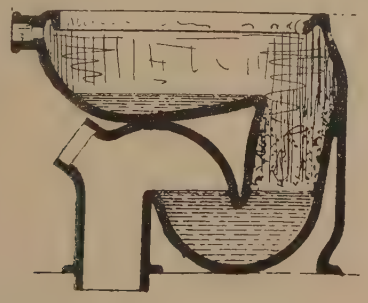

Fig. 54.

upon these being removed, and the defects remedied, the nuisance has ceased to exist. The general reason of the trouble is that the plasterer, knowing that his work near the floor will be obscured by the wood skirting, as a rule skips that portion, and the joiner following, cuts away, plugs the walls, or does not continue this skirting inside the part to be framed in, and therefore, should the enclosure be battened, or merely timber partitions, any smells from the apparatus when in use and foulness with which the floor, &c., is often saturated, or from defective joints will, ventilate up and around the hollows in the walls, and be conducted into the surrounding rooms.

The form of water-closet to be preferred is one so constructed as to give ready access to all its parts for cleansing, and to serve the three purposes of water-closet, urinal, and slop sink, thus for a certainty doing away with at least the last-named contrivance generally required in houses. It should be fitted with a balanced seat (Fig. 55) so

Fig. 55.

that the inconvenience caused from the spilling of slops may be avoided, and which, when required, can readily be put into position for use. The soil should be immediately immersed in a good volume and deep seal of water, and delivered directly into the drains without coming into contact with any exposed surfaces; there should be no sharp angles nor ridges which would collect filth or in any way interrupt the easy flow of the flush.

Difficulties in dealing with Measles. — Some difficulties in dealing with measles are cited in the report of Dr. W. J. Heslop, M.O.H. Urban District Council of Stretford. These difficulties, it appears, were due to the slight regard the general public entertains for this disease, the early stage at which it becomes infective, the lengthened period of incubation, the early age at which patients become attacked, causing difficulties in isolation, and the lengthened period of isolation required. "Our efforts to stem the epidemic," writes Dr. Heslop, "have been directed to endeavouring to confine the disease to the houses in which it occurred, by enforcing a strict quarantine on the infected house, together with the school closure, and the pointing out of the best means of disinfection to be undertaken by the parents, as it was found impossible for your Inspectors to disinfect each house, and also drawing the parents' attention to their legal responsibility in exposing infectious cases. At the commencement of the epidemic many people seemed to be unaware that measles was a notifiable disease, and although the township had been billed by posters and handbills, they seemed to have lost sight of this requirement, and it was thus that the epidemic spread so rapidly among the school children.

THE SUCCESS OF VACCINATION AND OTHER PREVENTIVE MEASURES IN SMALL-POX.

By MEREDITH YOUNG, M.D., Mast. Surg., D.P.H., Medical Officer of Health and Med. Supt. Crewe Corporation Hospitals.

(*Continued from page* 226.)

SOME interesting relations are brought out by a consideration of the condition of the once-vaccinated

class more particularly. I propose, therefore, to examine this class as to the relationship between the severity of attack and mortality at all ages, and (1) the number of vaccination cicatrices; (2) the area of scarring; (3) the condition as to foveation.

I.—*The number of Vaccination Scars.*

Exact information was obtainable with regard to 80 cases, and these may be classified in Table I.

Thus it is seen (1) that the percentage of discrete attacks is greater in persons with two scars than in those with one, and is greater in those with three scars than in those with two, whilst in those with four scars there is a decided advantage over cases with but one scar, though this does not hold good with the two and three scar cases. (2) The four scar cases, however, show a total absence of attack by the severer forms of the disease, and a total absence of deaths.

II.—Taking next the condition of the same 80 cases as regards total scar area, the particulars are as set out in Table II.

Thus the percentage of discrete attacks was large in cases with medium and large-sized scars, and the cases with the largest scar area showed the smallest percentage of confluent attacks, and a total absence of both hæmorrhagic attacks and deaths.

III.—*Foveation of Scars.*

Classifying the same cases on this basis we get the results shown in Table III.

Practically, the only safe conclusion we can draw from this is that almost three-quarters of the cases with foveated scars were discrete cases.

Taking together the number of scars and the

foveation, or otherwise, of these we have the following particulars of 78 vaccinated cases :—

Nature of scars.	Nature of attack.			Deaths
	Discrete.	Confluent.	Hæm.	
One scar foveated ...	5	2	—	1
,, unfoveated...	3	—	—	—
Two scars foveated ...	15	—	1	—
,, unfoveated...	2	1	1	1
Three scars foveated	22	2	—	—
,, unfoveated	5	3	—	1
Four scars foveated...	14	—	—	—
,, unfoveated	2	—	—	—
Total	68	8	2	3

Duration of stay in Hospital.—The evidence which this supplies on the influence of vaccination is, in this case at all events, not specially valuable. A rule was made, for example, in the early days of the hospital, that no case, however mild, should be discharged within fourteen days of admission, and this naturally lengthened the average duration of stay of the mild cases, whilst it did not affect the severe ones.

Another thing which to a considerable extent discounts the value of statistical data on this point is that, in a good many cases, a child a few weeks or a few months of age was admitted suffering from small-pox in a severe form. Owing to the fact of the child being breast-fed, or at least being too young to be separated from its mother, the latter was admitted with the child, and was re-vaccinated on admission, this being made a condition of admission.

The mother in several cases contracted a severe form of the disease, lasting perhaps for a week or ten days, but the precaution was not taken of entering her case up as having been admitted on the first day of the disease, and as having been discharged when the disease had terminated. The actual dates of admission and discharge in company with the child were entered, and therefore the duration of stay of the mother's mild case was made coincident with the child's severe case.

However, I give the averages subject to this explanation :—

	Average duration of stay in hospital.
Never-vaccinated cases	25 days
Once-vaccinated cases...	23 ,,
Re-vaccinated cases	17 ,,

The averages, it will be seen, are in favour of the once-vaccinated and re-vaccinated cases, but not to the same extent as they might have been had they been based on proper observations.

Particulars of Small-pox and Vaccination in Quarantined Persons.—During the epidemic, 83 families were kept in "quarantine" by the various Local Authorities concerned, and the statistics in regard to them give the most reliable evidence obtainable, perhaps, of the protection afforded by vaccination and re-vaccination, for the persons concerned had been exposed for, as a rule, at least two days to the infection of small-pox, and were living under the same conditions of life, &c. In the 83 families there were 277 persons at all ages. Of these 16 were unvaccinated, 78 were once vaccinated, and 183 were re-vaccinated ; and of the 277 persons 37 contracted small-pox.

Of 78 persons under 10 years of age 13 were unvaccinated, 54 were once vaccinated, 11 were re-vaccinated, and 16 contracted small-pox. Of 199 persons over 10 years of age 3 were unvaccinated, 24 were once vaccinated, 172 were re-vaccinated, and 21 contracted small-pox.

Of the 78 persons under 10 years of age, 5 once-vaccinated persons contracted small-pox, and all 5 cases were discrete and non-fatal. The incidence of attack on the once-vaccinated class was thus 9·25 per cent., and the case-mortality *nil*. Of the same 78 persons, 11, who were unvaccinated, contracted small-pox, and of these 11 cases 7 were confluent, 4 discrete, and 3 fatal. The incidence of attack on the unvaccinated class was thus 84·6 per cent., and the case mortality 23·0 per cent. Thus, the once-vaccinated persons under 10 years of age showed a more than ninefold greater immunity from attack compared with the unvaccinated when placed under the same conditions of exposure to the infection of small-pox. Of the 11 re-vaccinated cases none contracted small-pox.

Taking next the 199 persons over 10 years of age we find that of those who were once vaccinated 12 contracted small-pox, and, with the exception of 2 hæmorrhagic cases at advanced ages (43 and 59), all the attacks were discrete and non-fatal. The incidence of attack on the once-vaccinated class was thus 50 per cent., and the case-mortality 8·33 per cent. Of those who were unvaccinated all three contracted small-pox and one died, the other two having severe discrete attacks. Thus even in persons over 10 years of age, we have in the vaccinated a twofold immunity against attack, and a fourfold immunity from death by small-pox. Of 172 re-vaccinated cases 6 contracted small-pox, and in all cases the disease was discrete and non-fatal. The incidence of attack on the re-vaccinated class was thus 3·48 per cent. and the mortality *nil*. Thus the re-vaccinated class, as compared with the once-vaccinated class over 10 years of age, showed a fourteenfold immunity against attack and an eightfold immunity against death by small-pox, and, as compared with the unvaccinated class at the same age period, the re-vaccinated class showed a twenty-eightfold immunity against attack and a thirty-threefold protection against death by small-pox

(*To be continued.*)

Public Appreciation of Isolation Hospitals.—A striking testimony as to the public appreciation of isolation hospitals is reported by Mr. J. P. Humphery, Sanitary Inspector, Reigate. The number of cases removed as compared with the number notified were, removals, 103 ; notifications, 123. Of the number notified eleven occurred at St. Anne's Asylum, at which institution there is an isolation building for the treatment of such cases, and one was that of the cook at the isolation hospital. It will thus be seen that only eight cases were treated in private houses in the borough, which shows that the inhabitants are showing a growing intelligent appreciation of the benefits of having such cases removed. "It is worthy of note," adds Mr. Humphery, "that during the whole year I have not received one complaint as to the treatment of the children during their detention at the hospital, but quite the contrary has been the universal verdict."

PUBLIC HEALTH.

THERE was a good attendance at the St. Peter's Liberal Club, Arundel-street, Sheffield, on Monday, the 28th ult., when Dr. Hargreaves, one of the City Councillors for the ward, gave a lecture on "Public Health."

After a few opening remarks by the CHAIRMAN, Mr. R. Styring, who alluded to the importance of giving attention to the question of public health, and to the opportunity which Dr. Hargreaves, as a City Councillor, had of studying the question, the lecturer began with some observations on the necessity of personal attention to health. A complete system of hygiene for mankind must include consideration of the mental and moral faculties as well as the organs of the physical nature in a regular balanced order. The mental and moral faculties had great influence over the body, and the body had great influence in regulating them. He pointed out that there were four periods of life, to each of which general principles of health could be applied. Speaking on the first of these periods—infancy—he remarked that the average death-rate of children under the age of one year in Sheffield was 170 per 1000, and throughout the country it was 150. He dwelt on the need there was that the education of youth should include some teaching as to the laws of health. In adults, the whole of the powers, mental and physical, should be exercised, and life would be all the happier for it. A necessary precaution during this period was temperance—a sufficiency for health, but not indulgence. In old age, when the prime necessity was warmth, wine, or a little spirit might be permissible, but for healthy men at the adult period it was not a necessity. Going on to speak of legislation for the public health, he said it had been almost wholly confined to the Victorian era. With the exception of the Act with regard to the plague in 1603, the first legislation was in 1832, for protection against cholera, and this was followed by the Act relating to small-pox in 1840. He proceeded to describe the working of the various subsequent Acts, the first Public Health Act of 1848, the Local Government Act of 1858, the next Public Health Act of 1872, &c. He showed how, under these Acts, the pollution of rivers, the sanitation of dwelling-houses, the suppression of nuisances, and offensive trades, the notification of infectious diseases, and other matters were attended to. It was a curious fact that under the provisions with respect to offensive trades, the business of a rag and bone merchant could be dealt with, but no action could be taken in the case of private brick burning or the keeping of fried fish shops, though more nuisance might be caused by these trades than by the former. The West-street Hospital, he also mentioned, was not now the object of so much aversion from the inhabitants as when it was erected. They at first thought that by using the hospital they would be pauperised, but they had been educated beyond that, and instead of pressure being required to induce patients to go, it was the patients who complained that they could not be admitted. In 1890, 17 per cent. of the scarlet fever cases notified were admitted into the hospital; in 1896 the percentage was 59, and the percentage of enteric fever cases treated increased in the same time from 15 to 54. The present accommodation at West-street was very inadequate. There were 200 beds, and, calculated on the basis of one bed for every 1000 of the population, there ought to be 350; but even this provision would not be sufficient in the case of an epidemic. The lecturer was heartily thanked at the close.

Reviews.

Sewer Gas and its Influence upon Health. By H. ALFRED ROECHLING, C.E. Published by Messrs. Biggs and Co. Price 5s.

IT has long been known that emanations from sewers have a very powerful predisposing influence to many zymotic diseases, and, furthermore, although there is abundant experimental proof, in the case of animals, of the pernicious action of sewer gas upon health, yet the question has received upon the whole but scant attention from the hands of sanitarians.

A great deal has been written at one time and another with reference to the question of the influence of sewer gas upon health, but the published information has dealt invariably only with one or two aspects of this question, and not with the whole. This state of affairs the author has endeavoured to remedy in the treatise before us, and although he is fully aware that great gaps still exist in our knowledge of the subject, he has succeeded in throwing a great deal of light upon many obscure points. As pointed out by the author in his preface, the ultimate elucidation of this question must not be looked for from one standpoint only but from several, and it is to the harmonious working together of several specialists, such as the chemist, medical practitioner, bacteriologist, and engineer, that the answer must be looked for as to the sanitary bearings of this important subject.

The book contains chapters upon the history of the sewer-gas controversy, the present state of our knowledge respecting the chemistry of, and the changes fæcal matters undergo after evacuation, the composition of sewer gas, the bacteriology of sewer air, &c., and, although the knowledge displayed upon some of these points is of a somewhat superficial character, perhaps it is, on the whole, sufficient for the general illustration of the points connected with the points at issue.

In the second portion of the work the author deals with the experimental researches that have been published by various workers upon the subject, and he gives a very complete list of the home and foreign literature upon the influence of sewer air upon health.

In addition to a very full account of the evidence of the casual relations of sewer gas to typhoid fever and other diseases, a large number of authentic cases of mephitic and septic poisoning are given as the result of the action of sewer gas.

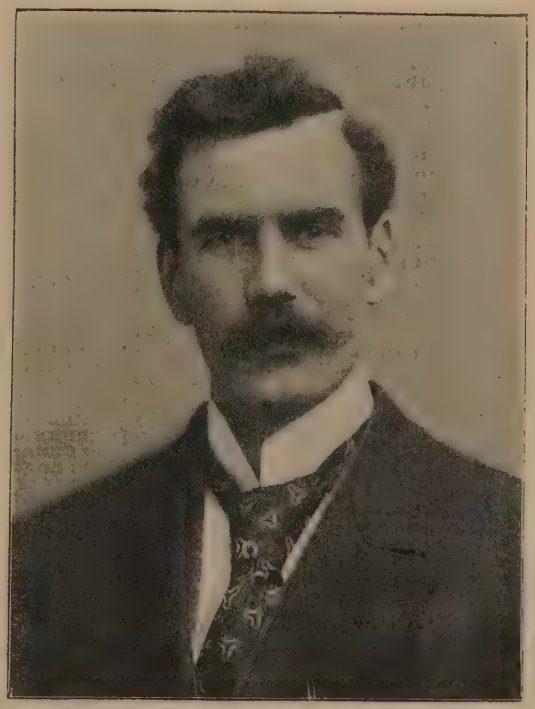
The author of this work deserves the thanks of all who are interested in the health of the community for the lucid manner in which he has collected and epitomised the whole of the information and evidence bearing upon the subject of the influence of sewer air upon health, and the book is one which should be studied by every student of sanitary science.

Coming Municipal Men.

I.—MR. FRANK LATHAM,

Assistant Surveyor, Margate.

MR. FRANK LATHAM, who is contributing a series of articles to this journal, is son of Mr. Albert Latham, M. Inst. C.E., Borough Engineer of Margate, and nephew of Mr. Baldwin Latham, M. Inst. C.E., of Westminster. He was born in Croydon, and educated at Margate College, and afterwards Thanet College. He served his articles as civil engineer and architect in the Borough Engineer and Surveyor's office, Margate, during which period he was admitted student of the Inst. C.E. Soon after completing his pupilage he started in Margate as Architect and Surveyor and Sanitary Engineer, and assisted generally in his father's private practice, during which time he made much progress, and was awarded an honorarium by the Margate Town Council for special sanitary work, reference being made by the Mayor and others (*Keble's Gazette*) of the admirable manner in which he had discharged his duties. He had on more than one occasion during this period charge of the surveyor's department in the absence of the Borough Engineer. He was awarded the certificate of competency in sanitary knowledge of the Sanitary Institute, and elected member in 1894, since which he has become Fellow of the Institute of Architects and Surveyors, and connected with other societies. In the following year he was appointed by the Town Council as Assistant Borough Surveyor of Margate out of 101 candidates, his duties being to examine plans for new buildings, and inspect the work when proceeding, and the same with the drainage of buildings with the new sewers, to attend and report to committee meetings, to be responsible for the correctness of the wages sheets, to conduct the correspondence of the surveyor's department, and to generally assist in the public works of the borough.



MR. FRANK LATHAM.

Mr. Latham has spent eight years in the offices at Margate, during which time he has been engaged in drainage works (the main scheme carried out by Mr. Baldwin Latham, and costing upwards of £80,000), house connections, about 3500, public promenades and conveniences, town improvements, road maintenance, sea defence works, waterworks and sewage pumping machinery (20 pumps, &c., in all), supervision of buildings and repairing of streets under the compulsory powers of the Private Street Works Act, and the usual routine of the public offices of this popular and progressive watering place.

The surveyor's department at Margate is always more or less full up with business. Amongst the principal public works now in hand are:—The building of new municipal offices; the laying out and constructing of roads and sewers, together with the erection of caretaker's cottage and lavatories in the new park; the sewering and raising of Dane and other roads; the reconstruction of sea defences damaged by the recent storm, and the preparation of a scheme for new sea wall at Cliftonville; the extension of the waterworks by a deep bore to a depth of 850ft.; and the design and construction of a high-level reservoir tank of capacity of 250,000 gallons; the overhauling and repairing of two Worthington pumps in connection with the sewerage system. A scheme for doing away with drain for Marine Drive houses, and connecting the properties with the High-street sewer; surveys and scheme, recently completed, for connecting sewer between Margate and Westgate. Surveys and plans for putting into repair, and taking over several private streets just finished, and others in hand; three new shelter seats being erected on the Queen's Promenade, &c. Besides this batch, the repair of roads is in full swing, and the tarring of paths and borough painting is about to commence. There have also, each year for three years, been about 250 plans for building operations submitted for approval, and about 200 new domestic buildings, together with a large number of additions to existing premises have been erected yearly. House drainage work is also regularly going on, and testing and connections with the public sewers are done daily by the Surveyor's department.

The Assistant Surveyor has, as stated in the *Thanet Times*, "evidently given the subject of sanitation much thought, and had some rather startling experiences," he having, besides his home training, spent considerable time in London and elsewhere on the matter.

Mr. Latham has a good knowledge of shorthand writing, which has been of much use to him, having obtained Pitman's proficiency certificate for a speed

of 120 words per minute. Some of his drawings have had good notice, his work being accepted by the South Kensington Educational Department for Art Masters' Certficate, and much credit is due to him for his designs in iron work. He also, besides his professional energies, assists as an instrumentalist at entertainments, and takes a leading interest in sports. He further devotes much time to his Masonic duties.

Mr. Latham has altogether, during his professional career, had an active life, and Mr. Leach Lewis, J.P., writing of his old pupil from Margate College, London offices, says that he certainly possesses indomitable pluck and perseverance.

Sanitary Inspectors' Associations.

LONDON.

AN ordinary monthly meeting of the Sanitary Inspectors' Association was held on Saturday at the Carpenters' Hall, London Wall, E.C. Mr. T. G. Dee (Westminster), the chairman of the Council, presided, and among those present were Messrs. H. Alexander, C. W. Raymond (hon. treasurer), S. G. Fairchild, J. F. Skinner, Ashdown, S. C. Legg, Henley, Barth, I. Young, W. H. Grigg, Jordan, Potter, Duck, McNair, and Mr. E. Tidman, C.E., the hon. secretary.

A number of members were elected, and in reply to Mr. Legg,

Mr. TIDMAN stated that the representations of the Association to the London County Council with respect to the low salaries proposed to be paid by the Vestries of Hackney and Battersea to Sanitary Inspectors they were about to appoint had not been altogether fruitless. The Public Health Committee of the London County Council had reported, recommending the Council to make representations to the Local Government Board as to the inadequacy of the suggested salaries, but upon the report coming up, Dr. Forman, the chairman of the Public Health Committee, had withdrawn the report, stating that it was hoped to attain their object in another way.

After some discussion, the secretary was requested to again communicate with the London County Council upon fresh aspects of the subject.

Mr. J. F. SKINNER read a paper upon "The Inspection of Dairy Farms." He said this was a matter of vital importance to large towns and cities, first with regard to the purity and freedom of contamination of the milk supplied; and, secondly, the wholesomeness of the flesh of the animals obtained from the farms and sold for consumption in large towns. At present the inspection of dairy farms was carried out in a most unsatisfactory manner, and in many instances it amounted to no inspection at all. In many rural districts the Sanitary Inspector was a poorly-paid official who only devoted a portion of his time to the duties of his office, and had a district so large that it was impossible for one man to properly do the work. In most cases the only inspection was made by the police, who occasionally visited them in order to ascertain if there were any animals suffering from contagious disease, but made no inspection as to the sanitary condition of the premises, or made any inquiries as to whether any of the employés were suffering from infectious disease. The milk was sent to the nearest town, and i was without guarantee of any kind. If there was proper supervision the country was the best place for dairy farms, and he thought the Sanitary Authority of every large town should be empowered to send their officers to inspect all dairy farms from which milk is sent into their district. If disease or insanitary conditions were discovered, then the Authority should have power to prohibit milk from that source being brought into the town. This would be a drastic measure, but until some such step is taken the inspection of dairy farms would never be properly carried out. The Infectious Diseases Prevention Act, 1890, was a step in the right direction, but it had two serious objections, viz., it was permissive, depending on the adoption by the Local Authority; and, secondly, by Section 4, the Medical Officer was empowered in certain cases to inspect dairy farms from which milk is sent into his district, but so many difficulties arose in putting the section in force that it was practically valueless. In fact, the Medical Officer must be in possession of evidence that some person in his district is suffering from infectious disease attributable to the milk supplied from a dairy without the district before he could exercise the powers conferred by the section. A more striking illustration of locking the stable door after the horse is stolen is seldom seen. Even when the inspection was made and evidence obtained more delay occurred. By the Dairies, Cowsheds, and Milkshops Order of 1885, various regulations were laid down, and these Mr. Skinner examined at length, afterwards drawing a vivid picture of the insanitary condition both as regards water supply, cleanliness, &c., of many dairy farm buildings in which cows are kept for the purpose of providing a milk supply. He referred to the milk stores and vessels, and gave a number of useful hints in regard to their inspection, and what should be required. He next dealt with the various contagious diseases from which cows suffer, and showed how these could be detected; and urged the keeping of a register of the whole animals kept for dairy purposes, as by this means a history of each cow could be kept.

Mr. S. G. FAIRCHILD moved a vote of thanks to Mr. Skinner, and referred to the difficulties of securing removal of infected persons from dairies, owing to the lack of accommodation at the Metropolitan Asylums Board hospitals. He thought the Board should be made to keep beds specially for these urgent cases. He also condemned the practice of mixing milks, as by this means a greater number of people were endangered.

Mr. I. YOUNG seconded the vote of thanks, and said if what Mr. Skinner had said was true in regard to the condition of dairy farms, the sooner all cows were kept in London the better.

Mr. SAUNDERS remarked that from his personal knowledge he thought the picture was under rather than overdrawn.

Mr. GRIGG reminded the members that in Belgium it was the universal practice to mix all milk together, and the small amount of scarlet fever and diphtheria in large towns like Antwerp seemed to show there was no particular danger in this practice.

Other members having spoken,

The CHAIRMAN said the fact that the Sanitary

Inspector in rural districts was a poorly-paid official, with much more work than one man could possibly get through, however anxious he might be to do his duty, was one explanation of the existing state of things. If there was sufficient inspection by officers who had permanent tenure of office, and need not fear anything from the members of the Local Authority, much of the evil would be removed.

The motion was heartily carried, and

Mr. SKINNER, in answering some of the points raised, pointed out that in rural places there was no isolation hospitals to which employés on farms could be taken when they fell ill from infectious disease. The fact that the Local Authorities entrusted with the administration of the law were composed of the farmers who sent the milk to market was a serious drawback to any effort to bring about improvement.

The usual private conference was then held, and the proceedings terminated.

SOUTH WALES AND MONMOUTHSHIRE.

A SPECIAL meeting of this branch was held in the Town Hall, Cardiff, on Saturday, March 5th. In the absence of the president (Dr. Williams, Medical Officer for the county of Glamorgan), who is indisposed, Dr. Walford, Cardiff, presided, there being a large attendance of officers and ordinary members. At the outset a vote of sympathy with the president in his illness was passed. A considerable number of gentlemen in Glamorganshire and Monmouthshire were nominated for election as hon. members, ordinary members, and associate members. Mr. John Powell, Surveyor and Sanitary Inspector, Pontypool, was elected a member; Messrs. Llewellyn Davies (Swansea) and T. Warren (Cardiff) were nominated as scrutineers for the ensuing year; and Messrs. Alfred Edgar Leyshon (Barry) and D. J. John (Pontypridd) were nominated as auditors. The meeting then discussed the Sanitary Inspectors' Superannuation Bill, 1898. A resolution was passed adopting the Bill, and deputations were appointed to interview all members of Parliament within the area of the Association with the view of getting them to support the measure. The president, treasurer, and secretary were appointed to proceed to London on the day when the Bill would be introduced into Parliament and interview the various members referred to so as to secure their votes in favour of the Bill.

DEVONPORT.—Since last week, when two lads were sent to the Royal Naval Hospital, no fresh cases either of measles or mumps have developed on the training ship Impregnable at Devonport, and it is hoped the outbreak has now been effectually checked. The outbreak of measles has not been confined to the boys, as about a dozen men of the Royal Marines serving in the Impregnable have been sent to the hospital suffering from the same malady. The Circe, tender to the Impregnable, although berthed at separate moorings about 300 yards distant, is also affected with both measles and mumps. On board both ships the boys are assembled every morning on the upper deck, and are separately inspected by one of the Medical Officers, and as a further precaution all newly-entered lads for the Devonport Division are being sent to the training ship Ganges at Falmouth, which fortunately is rarely visited by an epidemic.

Institute of Sanitary Engineers

A GENERAL meeting of the members of this Association was held at the Arbitration Rooms, Chancery-lane, March 3rd. The President, Mr. Spinks, occupied the chair. Mr. F. W. Lockwood, the lecturer, was unable to be present, and the paper was read by the chairman as follows :—

THE SANITARY ADMINISTRATION OF BELFAST.

Before dealing with the Sanitary administration of Belfast it may be well to describe in a very brief and general manner the leading features of that city.

Belfast is situated at the upper termination of the bay or Lough of the same name, and lies in a hollow surrounded on the west and north by hills ranging from 1000ft. to over 1500ft. above the sea, and by other hills on the south and south-east of three to four hundred feet in height. Upon the south-west is a wide, open valley of no great elevation, and upon the north-east and east lies the sea. About one-third of the town, including most of the older portion, is built upon an alluvial plain of estuarine mud and sand, through which runs the tidal river Lagan, and this plain scarcely rises in any part much above the extreme high-water level, and in some portions is even below it. The remainder of the town extends to a height of one or two hundred feet up the slopes upon the north and west. Several small mountain streams run through the city to fall into the Lagan, one of which, the Blackstaff, is of a tidal character during the greater part of its course through the city. The upper end of the Lough is covered, and was still more so until many of them were reclaimed, with mud banks left bare at low water. The average range of the tide is not great, being from about 8ft. to 11ft. The present quay and docks, the two great shipbuilding works, supporting between them a population of nearly 50,000, and many other large establishments are all built upon sites reclaimed from the tide. Until about ten years ago the town was drained direct into the Lagan, discharging at some ten or more outlets along its course, and these were necessarily blocked by the tide for a good many hours out of the twenty-four. When exceptionally high tide occurred, especially if combined with a heavy rainfall, the contents of the sewers in the lower part of the town were forced up through the street gullies, and in many instances into the yards and basements of houses, and as most of the houses in this low part were old and the house drains of old-fashioned brick construction, this damming back must unquestionably have produced a serious pollution of the subsoil and underground air beneath the buildings. It is needless to say that the Lagan had also become very foul.

The main drainage scheme, which is practically now completed, may be divided into two, or more correctly three, sections. The first, or high-level system, may be described as forming a rough semi-circle following the line of the base or escarpment of the rising ground, and probably draining about half the area of the town, and flows by gravitation

to a point at the north-east of the town, not far from the Northern Counties Railway Station. Here it is joined by the low-level system, which runs not far from and parallel to the course of the Lagan.

The drainage of the large area which lies upon the right bank of the Lagan is brought across under the river by a syphon, and joins into the low-level sewer at about the middle of its course. This combined low-level drainage is then pumped up into the high-level sewer, and the whole runs on by gravitation to a station formed in the mud banks near the edge of the Lough. Here it is received into a covered four-acre tank, so as to retain it during the time of high water, and to discharge it only after the turn of the tide, the discharge being stopped about two hours before low water. To further ensure its safe disposal it flows for another 1800 yards through a wooden shoot formed in the mud, and which terminates in the Pool of Garmoyle, a basin about two miles wide of comparatively deep water, at a distance of about four miles from the centre of the town. In connection with the tank an auxiliary pumping station has been provided to more rapidly empty the tank in the event of heavy rain floods. The low-level sewer being deep, and kept clear by pumping, has allowed of the shallow and defective street sewers in the older parts of the town to be relaid at an increased depth, and by this means the flooding of these parts and the saturation of the sub-soil has been to a great extent put an end to. This work is still going forward, and it will be some time yet before all the old sewers are deepened.

At the time the main drainage scheme was before Parliament the present writer, in a short review of it, raised a note of caution as to the possibility of detriment to the foreshores of the Lough from the discharge of so large an amount of drainage into a comparatively limited area, and the matter being taken up in more influential quarters, several measures of precaution, including the 1800 yards wooden shoot, were, during the carrying out of the scheme, adopted. Nevertheless, although the main stream of the river has, as might well be expected, become very much improved in purity, a cry has from time to time been raised that the injury feared to the foreshores has already taken place. It is not easy to judge whether there is any real ground for these complaints. The slob lands were unpleasant at certain times before, and remain so still, but I doubt whether they are really any worse than they were ten years ago. The City Surveyor, however, J. C. Bretland, Esq., M.I.C.E., in his report at that time recommending the scheme, pointed to the possibility at some future time of adopting some method of at least partial purification, and indicated that ample space would be available in the vicinity of the tank and could be reclaimed for such a purpose. It is quite conceivable that with the rapid progress which the bacterial system, for instance, is making in public favour, that a few years may see the attempt to dispose of the grosser impurities by a rapid biological action before the sewerage is discharged into the sea.

There is another point with regard to the discharge of the sewage here. Thirty, and even twenty years ago, a very large quantity of the coarser shell-fish, mussels, cockles, and periwinkles, were gathered from these various banks and foreshores. As an eminent zoologist, Mr. R. L. Patterson, F.L.S., several years ago pointed out, so large a number of mussels were sent over as bait for the Scottish fishermen, that they nearly became extinct, but recently, after the trade ceased, as being no longer profitable, they have begun to increase again, and will doubtless once more be appropriated as food for the masses. It is well known that many cases of typhoid have been traced to sewage-contaminated oysters, and mussels and cockles must be quite as capable, under similar circumstances, of spreading the infection. These remarks are in no way intended as condemnation of the main drainage system, but simply as minor considerations which may yet call for future attention.

In treating of the sanitary administration of Belfast, it must first be explained that the city government is to some extent in a transitional state, on account of the very large addition which has recently been made to the city area.

The municipal boundaries, which were in the year 1885 fixed so far in the country as to allow of a very great extension in every direction, have nevertheless by the rapid growth of the town been so much encroached upon, and various outlying suburbs and villages have become of such importance as to render a very large extension of the city area imperative, and this came into effect in November, 1897. Before then the city area was about 8474 acres, it has now been increased to about 16,503 acres. This, of course, will involve a considerable increase in the staff of Inspectors and other officials, and will also, especially at first, bring some districts, at present—at least in part—of a rural character, under the city administration.

The sanitary work of a large city such as Belfast may be divided in the main between two great departments. Owing to the very rapid extension of the city, the first of these, administered by the City Surveyor and his staff, under the control of the Improvement Committee of the City Council, has been of even greater extent and importance than in most towns, and may be said to be devoted to construction, and has to do with the regulation of all new roads and buildings. The second, or Public Health Department, directed by the Medical Officer of Health and the executive sanitary officer, may, in contradistinction to the former, be said to be devoted to destruction, or the searching out and abolition of nuisances. Possibly a better way of putting it might be to say, that the duty of the former is prevention, and that of the latter cure.

The City Surveyor's department has, however, had a great deal to do in the way of destruction, by sweeping away slums and opening out congested areas, and there is no reason to suppose this work is yet at an end. They have also erected four extensive and admirably-appointed suites of public baths, and are now projecting a fifth.

The regulations for the erection of new buildings are very complete, and the chief points in which they more particularly bear upon sanitary matters may here be briefly summarised. Omitting all those provisions which deal with such questions merely as strength and statistical safety, I number the various items for convenience.

(1) All new buildings must be of good materials, and especially mortar. The exact standard does not appear to be defined, and much is clearly left to the knowledge and discretion of the officials.

(2) No made ground is to be allowed; or at least if in the opinion of the officer it is bad, it is to be removed, and in other cases covered with

asphalt, concrete, or similar damp-resisting material. This regulation has led to much controversy, not certainly as to whether it is a proper one—upon that there is no doubt—but as to whether it has been properly enforced. I shall certainly not repeat the charges that have been freely made in certain quarters as to connivance at the violation of this rule. The most honest officials, after all, are only human, and may not always be able to overtake their work, and may sometimes be caught napping. There is no doubt, however, that in very recent years a very large quantity of road sweepings, most of it we will suppose of a harmless nature, has been used to fill up hollow and swampy ground, and with this, owing presumably to a want of a sufficiently vigilant inspection, a large quantity of refuse from other quarters has been, quite contrary to the regulations, put down—enough often to render the whole mass most objectionable, and through this deposit several streets have been cut. I believe that up to the present the Improvement Committee have succeeded in preventing houses from being erected upon the worst of these spots, but I fear that in many less conspicuous instances they have not enforced their own bye-laws as strictly as could have been wished, or as in the interest of the public health was desirable. I may have to refer to this topic later on.

(3) There are strict rules as to suitable construction, as to preventing damp rising from below, or getting into walls through the roof or spouting, &c.

(4) Every apartment occupied as a dwelling, or in which persons regularly work, is to be of reasonable size, and no ceiling is to be less than 8ft. in height.

(5) Every apartment is to have some means of ventilation, either by open fire-place, or, failing that, a ventilator in the outer wall of each room, and a window made to open at the top. These last two provisions are no doubt excellent, but in an artisan population which delights in stuffiness are practically a dead letter, as there is nothing to hinder, as is usually the case, the ventilator being pasted over the moment the house is occupied, and the regular opening of windows is not, and hardly could be, made compulsory.

(6) No drain is to pass under a dwelling, except by special leave in exceptional cases, when it must be an iron pipe surrounded by concrete. This rule is very strictly enforced. All drains everywhere must be inspected before being covered up. I do not think, however, this inspection is quite so rigid as it might be—at least, for instance, in not always applying the water test. The tendency is, however, to greater care, which comes with increased knowledge and experience on the part of the Inspectors.

(7) All traps must be of the modern sort, and to every house (now modified under certain conditions as to ventilation and inspection to include a row) must be a disconnecting trap of Buchan's type.

(8) Soil pipes must always be outside and of full 4in. diameter, carried up the same width to a proper height above eaves.

(9) All wastes must be outside and discharge over gullies 18in. from wall.

(10) All water-closets must be in outside wall, and ventilated.

(11) Must have separate flushing cisterns, and the type of water-closet must be approved of.

(To be continued.)

General News.

HOME.

NOTICE.—On and after 31st March next the Annual Subscription to this Journal will be raised to 12s. 6d. to all NEW Subscribers. NO ADVANCE will be made to our friends whose names are entered on our Subcription list prior to that date, so long as they continue to Subscribe.

BRAMLEY.—The Guardians have decided upon seeking a loan for £1000 for the furnishing of the new hospital.

MALDON.—Plans for the proposed infectious diseases hospital, the building of which will cost from £950 to £1000, have been approved provisionally.

CLEWER.—The Local Government Board propose to hold, on March 15th, an inquiry into the matter of obtaining by compulsory powers a piece of land at Clewer for the purpose of erecting a pumping station.

COLERAINE.—A Local Government Board inquiry has been held concerning the application of the Town Commissioners for sanction to a loan of £5000 for the purpose of providing an additional water supply for the township.

KIRKBY STEPHEN.—A Local Government Board inquiry has been held at Kirkby Stephen into the application of the East Westmorland District Council for sanction to borrow £700 for purposes of water supply for the township of Kirkby Stephen.

MIDDLESBROUGH.—Dr. Malcolmson, Medical Officer of Health for Middlesbrough, died suddenly on Tuesday, the 1st inst. The increasing smallpox in the town had produced overwork and worry, which quite undermined his health. The victims to the epidemic now number 685.

CREWE.—On account of a serious outbreak of measles, several schools have had to be closed. A joint meeting of the Health Committee of the Town Council and the Schools Attendance Committee was held recently, and it was decided to close St. Barnabas' Infants' School and Pedley-street School for three weeks at least.

CARDIFF.—At a meeting of the Health Committee of the Cardiff Corporation held on February 22nd, the plans were inspected and afterwards passed for the extension of the sanatorium. Three pavilions will be erected, and there will be accommodation for sixty extra beds, making a total of 132 beds for the sanatorium. The cost is estimated at £24,000.

ROWLEY.—At the last meeting of the District Council a letter was received from the Local Government Board, stating that it demurred to sanctioning the desired loan for house connections until the scheme was amended by the addition of ventilating shafts, inspection chambers, lampholes, &c., but after being informed that the part of the drainage for which the loan was required did not need these things, it gave its sanction to a loan of £10,000 for that part of the house drains which the Council decided upon.

COCKERMOUTH.—A Committee of the Cockermouth, the Rural, and the Workington Authorities has been appointed to arrange for an increased water supply.

ERDINGTON.—At a recent meeting of the Council, the Health Committee reported that it had carefully considered the question of the cost of scavenging the district, and recommended that three tip wagons be provided at a cost of £150. With hire of team and manual labour it was stated the total cost would be about £800 for the first year.

EAST ASHFORD.—In reply to the Guardians, the Local Government Board states that it is part of the duty of Medical Officers of Health to make themselves acquainted with the character of the water supply of their districts, as one portion of their responsibility in informing themselves of all the influences likely to affect the public health. The Guardians have contended that Medical Officers should analyse samples of water when required to do so.

MAIDSTONE.—The Lord Mayor of London has remitted to the Mayor of Maidstone £927 8s. 9d., being the balance of the fund recently raised at the Mansion House for the relief of the sufferers by the typhoid epidemic at Maidstone. The Mansion House fund is now closed, but the Mayor's fund at Maidstone still remains open, as the widows' and orphans' branch of it requires to be largely augmented before adequate provision is made for these sufferers.

ST. ANDREWS, FIFE.—The Sanitary Committee have consulted Mr. Walter Brenan, C.E., Oban, engineer to the County Council of Argyll, as to the disposal of the sewage of the town. Reports and plans have been presented, with estimate of cost for dealing with same by an intercepting tank and pumping of the low-level sewers. The Town Council have agreed to delay proceeding with same to allow of an experiment on the tidal outfall pipe with an "interceptor" proposed by one of the Councillors.

FALMOUTH.—Dr. W. K. Bullmore, the Medical Officer for Falmouth and Truro Port Sanitary Authority, in his annual report for 1897, states that 791 ships, representing an aggregate of 425,372 tons, visited the port. There had not been any infectious or contagious disease brought into the district, and there was comparatively very little sickness amongst the crews of vessels arriving. The total number of cases treated during the year at the Royal Cornwall Sailors' Home was sixty-two, of whom ten suffered from accidents and injuries, ten from scurvy, one from fever, fifteen from beri-beri, and twenty-four from minor ailments.

HANDSWORTH.—A few figures contained in the Medical Officer's report have a strong bearing on the not infrequently expressed belief that Handsworth is not healthy. In the twenty years from 1871 to 1891 the population increased from 14,947 to 32,756, and at the present time it is computed to stand at 41,600. During the same period, and, be it noted, along with the increase of population, has gone a decrease in the death-rate, which was 15·9 per 1000 in the five years 1871—75, and fell gradually during each succeeding five years to 12·2 at the end of 1895. During 1896 it went up to 13·4, but during last year it fell to 12·1, the lowest for more than a quarter of a century.

EDINBURGH.—The Edinburgh Authorities, who have been experimenting with the Reeves system for preventing sewer gas on the water of Leith purification sewer for several months past, have now decided to order an extended installation of fifty apparatus.

CLACKMANNAN.—At a special meeting of the County Council held recently at Alloa, it was agreed to authorise a loan of £20,000 from the Local Government Loan Commissioners in connection with the county's new water scheme. Subsequently the Standing Joint Committee met and confirmed the resolution of the County Council.

LOCH KATRINE.—The monthly report on the quality of Loch Katrine water, prepared by Professor E. J. Mills, D.Sc., F.R.S., Glasgow and West of Scotland Technical College, has been issued. The results are returned in parts per 100,000:—Total solid impurity, 3·16; organic carbon, 0·170; organic nitrogen, 0·024; nitric nitrogen, 0·002; ammonia, 0·000; total combined nitrogen, 0·026; chlorine, 0·74; hardness, 1·27; temperature, 6·0 deg. Cent. = 42·8 deg. Fah. The water was sampled on Februrary 15th. It was light brown in colour, and contained a little suspended matter.

ABROAD.

JOHNNESBURG.—The sanitary condition of Johannesburg evidently requires the prompt attention of the new Town Council, for we notice that the death-rate for January last, amongst the white population of 50,000, reached the excessively high figure of 44 per 1000. The endeavours now being made to establish a destructor are made none too soon, but the spirit that sometimes prevails in this country with regard to these modern Gehennas, and which now is rampant at Scarborough, seems also to exist in the Transvaal, for when the decision of the Town Council with regard to a site was submitted to a town's meeting it was rejected, and a poll has been demanded. Lengthy letters containing all manner of suggestions appear in the local Press—a custom, too, which isnot unknown in this country. It seems to us another raid is required, but not upon the "oof bird" this time, but upon the deadly microbe and the undertaker.

Personal.

MR. J. F. FREW has been appointed Medical Officer for the sixth district of Oldham union.

MR. F. W. MARTIN has been appointed Medical Superintendent of the Brighouse Joint Hospital.

MR. J. R. HATFIELD has been appointed Medical Officer of Health for the rural district of Cherbury.

MR. J. M. COATES has been appointed Vaccination Officer for the Stanway district of Lexden and Winstree union.

G. A. BRANSON, L.R.C.P., has been appointed a Public Vaccinator at Bendigo, Victoria, Australia, vice Mr. J. Amess, resigned.

DR. H. M'KAY has been appointed Medical Officer for the south-east district of Sheffield union, in room of Dr. Strickland, resigned, at a salary of £75 per annum.

DR. BROSTER has been reappointed Medical Officer of Health for the urban district of Wirksworth.

O. B. TRUMPER, M.B., Ch.B. (Vict.) has been reappointed Medical Officer for the Market Rasen urban district.

DR. DEVEREUX has been appointed Medical Officer for the Tewkesbury district at a salary of £80 per annum.

J. G. E. COLBY, M.B., L.R.C.P., has been reappointed Medical Officer of Health for the rural district of Norton.

MR. S. PROTHEROE has been appointed Inspector of Nuisances for Hereford, at a salary of £150 per annum.

H. L. THURNELL, L.R.C.P., M.R.C.S., has been reappointed Medical Officer of Health for the borough of Gravesend.

GREGORY SPROTT, M.B., B.Ch. (Glasg.), has been appointed Officer of Health for the district of Queenborough, Tasmania.

J. F. HOLDEN, M.B., C.M. (Edin.), has been appointed Medical Officer for the fourth sanitary district of the Preston union.

S. T. TAYLOR, M.B. (Lond.), L.R.C.P., M.R.C.S., has been reappointed Medical Officer for the Chingford urban district.

S. ANDREWS, L.R.C.P., M.R.C.S., has been reappointed Medical Officer for the second sanitary district of the Basingstoke union.

DR. M'CALL, of Conisbro', has resigned his appointment as Medical Officer to the Cadeby portion of the Denaby Main Collieries.

MR. E. V. PERRY, of Reepham, has been appointed Medical Officer for the Witchingham district of St. Faith union, in room of Dr. H. H. Back.

MR. HENRY SIMMONS, Corporation gas manager, Colne, has been appointed manager of Bury Gasworks, at a commencing salary of £350 per annum.

THE Local Government Board has sanctioned the appointment of Dr. Robert Browne as Medical Superintendent Officer of Health for the township of Rathmines, at a salary of £50 a year.

W. EVELYN JAMES, L.R.C.P. (Lond.), M.R.C.S., has been appointed Medical Officer and Public Vaccinator for the parish of Mynyddislwyn by the Newport (Mon.) Board of Guardians.

MR. PATRICK O'NEILL, formerly manager of Lockerbie Corporation Gasworks, has been appointed by the directors of Lochmaben Gas Company manager of the gasworks in that burgh.

DR. HUNTON has been appointed Medical Officer of Health for Sedgefield, in room of Dr. Sheraton, who has held the position to the entire satisfaction of the Guardians since 1864. Dr. Hunton had been Medical Officer for the Stockton union for some time.

AT the last meeting of the Sutton (Surrey) Urban District Council it was unanimously resolved to apply to the Local Government Board for a loan for the construction of additional bacteria filters, on the plans prepared by the Engineer and Surveyor to the Council, Mr. C. Chambers Smith, and of sufficient capacity to treat the whole of the daily sewage flow.

Sewerage Schemes.

[TO MUNICIPAL ENGINEERS AND SURVEYORS.—The Editor will be pleased to receive items for publication relating to sewerage schemes projected or inaugurated, together with explanatory diagrams or photographs. The former should be drawn and lettered in black ink.]

MR. E. W. IVES, C.E., of Derby, has been retained by the Donnington District Council to prepare a scheme of drainage and sewage disposal.

A LOCAL Government Board inquiry has been held at Bradford-on-Avon into the alleged default of the Urban Council to provide the district with sufficient sewers.

THE Stratton District Council has appointed the Sanitary Inspector (Mr. R. Peardon) as clerk of the works in the new scheme for the disposal of Stratton sewage, which will be carried out by Mr. Ross Heard, of Bude.

A LOCAL Government Board inquiry has been held at West Bromwich concerning the application of the Town Council for sanction to apply £3500 of the balance of a loan raised by it for works of sewerage and sewage disposal in defraying the cost of certain works of sewage disposal.

A LOCAL Government Board inquiry has been held at Pembury with reference to a petition requesting the Board to issue a Provisional Order empowering the Tonbridge Rural Council to put in force the Land Clauses Act in order to acquire certain land for the purpose of a sewerage scheme for Pembury.

AT a recent meeting of the Yeadon District Council, a resolution passed some time ago adopting Adams's lift for dealing with the New Scarborough sewage was rescinded, and a further motion was passed accepting an offer from the Guiseley Council to take the sewage into its disposal works, the agreement to be subject to the approval of the Local Government Board.

A LOCAL Government Board inquiry has been held at Fenny Stratford into the application of the Urban District Council for the issue of a Provisional Order to empower it to put in force, with reference to certain lands required for the disposal of the sewage of the district, the power of the Lands Clauses Acts with respect to the purchase and taking of lands otherwise than by agreement.

AT the last meeting of the Hereford Town Council the Sanitary Committee reported a long reply from Hay Sanitary Authority with regard to the request of Hereford that Hay should remove its sewage from the rivers Wye and Dulas, but that the pollution was not denied, and there was no promise to remedy the evil. The Council instructed the Town Clerk to take legal proceedings.

A REPORT made by the County Medical Officer to the Sanitary Committee of the Worcestershire County Council, having reference to the pollution of the river Cole, has been referred to as extremely satisfactory from the point of view of the Yardley District Council. It stated that the pollution was entirely due to the overflow of the Birmingham sewer at Yardley Bridge, and that the allegation that nine-tenths of the offensive matter came from Yardley could not be substantiated.

A BILL to make more effectual provision for the prevention of the pollution of rivers and streams, which has been introduced into the House of Commons by Sir F. Powell, is supported by Sir H. Howorth, Sir J. Brunner, and Mr. Brigg. The principal object of the Bill is to improve the law for preventing the pollution of streams by extending to County Councils, Joint Committees, and River Boards in England the main provisions of the Mersey and Irwell Act of 1892, and the West Riding of Yorkshire Rivers Act of 1894.

THE Rivers Committee of the Manchester Corporation have had under consideration various suggestions for disposing of the sewage of the city. The rejection of the culvert proposal has, of course, placed them under the necessity of formulating another scheme. It has been decided to make a trial of new filter beds at a cost of £28,000, and if the experiment is regarded as satisfactory, a general scheme of filtration will be forthcoming. It is stated that the ultimate cost may be as much as £500,000.

A LOCAL Government Board inquiry has been held in respect of an application made by the Windsor Rural District Council for a Provisonal Order to empower that Authority to purchase land near St. Stephen's School from the Clewer estate, for the purpose of erecting thereon an engine-house and pumping-station, in connection with Mr. Fowler's scheme of drainage for the parish, adopted by the District Council. The proposed ejection station will be in the ground at the junction of Oxford-road and Vansittart-road, and will be worked by an engine erected in a proper house on the field behind Gerald-villas (a part of Vansittart-road) a little beyond what is called Clewer Ditch.

THE new sewage works of the Sutton-in-Ashfield Council have now been formally opened. Mr. McWilliam Bishop, the Town Engineer and Surveyor, who designed the scheme, described the process adopted, which is known as the "International," combing precipitation followed by filtration, the sewage being first treated with ferozone, and then passed through Candy circular tanks with automatic sludge-removal apparatus, clarifiers, and finally purified by polarite filters, whereby rapid oxidation is effected. The effluent is remarkably clear, and the chemical analysis indicates a high degree of purity. The dry weather flow is about 260,000 gallons per day, and of a highly concentrated character, being at the rate of twenty gallons per head for a population of 13,000. Much satisfaction is expressed by the Council with the work, which has been carried out with such marked success by their own Town Engineer, Mr. McWm. Bishop.

A COMMITTEE has been appointed by the Meriden Rural District Council to consider the question of Fillongley drainage.

THE Local Government Board has sanctioned the loan for the sewerage scheme for Stapleford and Sandiacre. The cost is about £11,000.

THE engineers to the Taff Vale Windsor Dock scheme of the present session have prepared for the information of Parliament detailed estimates of the cost of the whole of the works comprised within the scheme. The aggregate estimated cost of these works is set down at £1,232,399, as compared with £854,000, which is the estimated cost of the scheme of last session. The actual cost of the proposed dock, together with the lock entrance and the diversion of the river Ely, the latter of which formed no part of the scheme of last year, will, it is estimated, require £1,081,455, as compared with £708,800.

THE Shipley District Council has decided upon a comprehensive scheme for the destruction of town's refuse, the purification of sewage, and the generation of electricity. For several years the work of ashpit cleansing has been carried out by the Local Authority at Shipley, but hitherto nothing has been done in the way of burning the refuse. It is proposed to deal with the solid refuse and the sewage on the same site, some thirty acres of land having been acquired for the purpose at Dock Field, which is between the river and the Leeds and Liverpool Canal, and adjoining the Midland branch line to Ilkley. It is intended to construct here sewage works, and in connection therewith to provide for the generation of electricity. In deciding upon a scheme the Council was met at the outset with the difficulty that all the sewage must be pumped before treatment, but an arrangement has been suggested by a member of the Council which will effect a very material economy in the working out of the scheme. Hitherto it has been the custom in electricity works to construct wells for the water which is used for condensing purposes, the water having to be drawn from the wells for this purpose. At Shipley it is intended, however, to adopt the novel and practical idea of causing the sewage to serve instead of water for condensing, and thus to avoid the expense of constructing wells. The sewage will be raised from the tank at the end of the sewers to a height of some 40ft., and will flow into a series of tanks, through which it will fall by gravitation, and will then be discharged into the river purified. The power required to work the necessary pumps it is proposed to obtain from the burning of the refuse. The steam thus raised will not only be sufficient, it is computed, to lift the sewage, but is expected also to leave a margin of upwards of 150-horse power, and this it is intended to use for the generation of electricity. The steam will be utilised in a compound condensing engine of 200-horse power, a surface condenser being used for condensing the steam. The sewage will pass through the condenser on its way from the receiving tank to the higher level, the condenser being exhausted by an independent electrically-driven air pump. It is also proposed to drive the centrifugal sewage pumps electrically.

ORIGINALLY it was intended to incorporate the sewerage of Cossall with that of Ilkeston, but this was found impracticable, and separate plans have been prepared by Mr. Walker, of Nottingham, approved by the District Council, and sent to the Local Government Board together with an application for a loan of £2300 for carrying out the work.

THE Local Government Board having been petitioned by the Midhurst Rural District Council to issue a Provisional Order to empower it to put in force with reference to certain lands required by it for the disposal of the sewage of Midhurst and parts of Easebourne and West Lavington, the powers of the Land Clauses Act with respect to the purchase and taking of lands other than by agreement, an inquiry has been held into the matter.

Lighting.

THE Clonmel Corporation has decided to expend £500 on improving the gas works, which it has lately purchased.

A LOCAL Government Board inquiry has been held at Much Wenlock into an application by the Town Council for a Provisional Order to purchase the gas works.

THE Derby School Board has instructed the Electric Lighting Committee of the Corporation to prepare a specification for lighting the Board Schools.

THE Eccleshill Gas Company, having refused to grant a reduction in the price of gas, the District Council has approached the Bradford City Council with a view to arranging terms for the Corporation to supply the public lighting of Eccleshill.

THE Darlington Town Council has confirmed the agreement made by the Gasworks Committee to engage the services of Professor Kennedy to inquire into and advise as to the best system of electric supply for the lighting of the borough.

THE electric lighting question was considered at a special meeting of the Greenock Police Board held recently, and it was resolved to make application to the Board of Trade for an extension of time in order to permit of the matter being more fully considered.

AT a recent meeting of the Cleaning and Lighting Committee of Edinburgh Town Council, it was agreed to remit the request of the Gas Commissioners to be allowed to experiment in lighting the streets of the city with the incandescent light to the Lighting Sub-Committee. There were remitted to the same Committee the various motions made by members of Council at the previous meeting on the subject of the extension of the electric light for public purposes in various parts of the city.

A LOCAL Government Board inquiry has been held at Selby into an application of the Urban District Council for a Provisional Order, under the Gas and Waterworks Facilities Acts, to undertake certain extensions and improvements to the gas-works plant.

AT a recent meeting of the Gas Committee of the Dundee County Council, the question of reconstructing the gas works, and of introducing the carburetted water gas, was discussed. A motion was carried which stated that, having regard to the additional ground now acquired, a recommendation be made to the Council to set aside any proposal for carburetted water gas in the meantime, and to instruct the manager, after consultation with Mr. Fowlis, Glasgow, to bring up plans and estimates for extensions and improvements on the works in order that an additional supply of coal gas might be produced.

THE question of electric lighting and a dust destructor for Hackney, involving an initial expenditure of at least £250,000, after having been under consideration for six years, has at last been settled. The Vestry has rescinded all the resolutions which prevented its parting with the Electric Light Order, and has decided to transfer it to a private company, and have inserted the following clause in the agreement:—"The Vestry to transfer the whole of its powers under the Provisional Order, as far as they relate to the area of the Vestry of Hackney; the Vestry to undertake not to apply for nor consent to any other application for an order for the parish of Hackney."

THE Perth Police Commissioners have adopted the following minute of the Sub-Committee:—"That after consideration of the amended plans, the Sub-Committee are not satisfied that the gas works can be carried out to the satisfaction of the Commissioners at a reasonable figure, and they recommend that an approved gas engineer be invited to visit Perth and report as to plans for the erection of gas works suitable for Perth at a cost not exceeding the sum available according to the borrowing powers under the Act; further, instruct the clerk to write to West's Gas Improvement Company, Limited, explaining the difficulties that had arisen through the manager having greatly exceeded the estimated probable cost of the new gas works, and ask them to state how far they were prepared to meet the Commissioners in tiding over their difficulties."

Obituary.

DR. MALCOMSON, M.O.H., MIDDLESBROUGH.

WE regret to announce the demise of Dr. John Andrew Malcomson, M.A., M.O.H. for the borough of Middlesbrough, which took place suddenly on the morning of the 1st inst. The deceased gentleman, who was greatly esteemed in the town and district, had been Medical Officer of Health for the borough since 1873. He was to all appearance a man of strong constitution, but it was noticed last week,

that the strain in regard to his duties connected with the present epidemic of small-pox in Middlesbrough was telling upon him. On the previous night he appeared more cheerful and in better spirits, and between 11 and 12 o'clock he lay down on the sofa, and had some conversation with Dr. Bateman and one or two other friends who were in the house. He afterwards went to bed but rose again, and at eight o'clock the following morning a maid in opening the drawing-room door found him lying on the sofa breathing heavily, and evidently very ill. A doctor was sent for, but before his arrival Dr. Malcomson expired. Death was afterwards certified to be due to cerebral apoplexy, and an inquest will not therefore be held. The deceased gentlemen was forty-six years of age. He was married ten years ago to Miss May Smith, daughter of Dr. Smith, of Derry, and leaves a widow and three children—a son and two daughters—the eldest being about eight years of age.

Correspondence.

We do not in any way hold ourselves responsible for opinions expressed by our correspondents

RELATIVE COST OF WORKS OF SEWAGE DISPOSAL.

(*To the Editor of* THE SANITARY RECORD.)

SIR,—It is generally accepted that considerable latitude must be allowed to patentees when advocating their specialities, and that many of their claims must be taken *cum grano salis*. That Messrs. Cameron, Commin, and Martin, the patentees of the Septic tank, do not intend to assume exemption in this respect, is, I think, evident from their letter in THE SANITARY RECORD of February 18th.

Had these gentlemen confined themselves to a laudation of the Septic tank and its superiority (in their estimation) to that of other systems, no exception would have been taken thereto, which would doubtless have been accurately judged for what it was worth by your readers.

When, however, the patentees indulge in framing for themselves an estimate of the cost of the bacterial system of sewage treatment as adopted at Sutton, of which they are evidently not *au fait*, in order to effect a comparison to their commercial advantage, that licence which is allowable under certain circumstances becomes somewhat, it will be admitted, overstrained.

Inasmuch as I have been responsible for the construction of the bacteria filters at Sutton for the Council—who are indebted to Mr. Dibdin for the generous manner in which he has placed his advice and the results of his wide experience in the treatment of sewage at their disposal—I am advised by others who are well acquainted with both the Sutton and the Exeter processes that it is my plain duty to your readers and to Local Authorities generally not to allow the statements of the Septic tank patentees to pass without correction.

In doing so, however, it is necessary to observe that there is no intention of depraising any particular system. The Sutton process is not a proprietary one. With the results obtained by it the Sutton Council are eminently satisfied. Whether it is adopted by other Local Authorities or not is a matter of indifference pecuniarily to anyone connected with it, and the process may be copied by any other Council without payment of royalties to any patentees. Replying to the several matters raised, I have, to facilitate ease of reference, reproduced in Column A, the points raised by Messrs. Cameron, Commin, and Martin, while in the parallel column B are my observations thereon :—

A	B
(1) "We need hardly point out that it is impossible to lay down any scale of cost which will be generally applicable under the widely different circumstances which are met with in different places."	(1) The patentees of the Septic tank issued a pamphlet in which they say "the cost of new tanks may be estimated at £70 to £80 per 1000 for populations between 5000 and 10,000, and proportionately for larger or lesser numbers. When filtration of the effluent is necessary, the cost of suitable filter beds varies from £150 to £250 per 1000 of the population."
(2) "The works at Exeter have been designed to deal with the sewage of 47,000 people, the maximum flow provided for being 2,500,000 gallons per day. They are estimated to cost £13,940, including grit chambers, conduits to tanks and from tanks to filters, penstocks, &c., but exclusive of engineering charges. The cost is, of course, greater than for a place of the same size sewered on the separate system, in which not only would the works be smaller, but no provision for removing road grit would be necessary."	(2) Whether a place is sewered on the separate system or not does not affect the cost of works when the quantity of sewage capable of being treated is taken as the basis for comparison. As the Exeter works are designed to treat 2½ million gallons of sewage daily, and their estimated cost is £13,940, this is equivalent to £557 12s. per 100,000 gallons (exclusive of engineering charges and royalties). In Sutton works coarse-grain and fine-grain filters capable of efficiently purifying 100,000 gallons per day cost £390 (this includes all charges), or £167 12s. per 100,000 gallons less than in the Exeter process.
(3) "It is assumed, under the Exeter system, that royalties will be payable to the patentees. No royalty is included in the sum quoted above, but we may state that the royalty that we should charge in such a case would not bring the cost of our works up to that of works under the Sutton system."	(3) In any instance where the Sutton system is adopted, no royalty charges are incurred, as is the case where the Exeter system is adopted. Even without royalties the latter system costs more than the former, as shown above. In September, 1896, the patentees were prepared to accept from the Sutton Council a royalty of 3d. per annum per unit of population, which worked out to £150 per annum for royalties alone. The royalty charges of the Septic Tank Company are now, I understand, fixed at £30 per cent. on the cost of the works. Therefore to the cost of £557 12s. per 100,000 gallons, as given by the

A	B
	patentees, must be added £167 5s. 6d. for royalties, making the cost per 100,000 gallons £724 17s. 6d., as against £390 on the Sutton process, or a difference of £334 17s. 6d. per 100,000 gallons of sewage.
(4) "In the Exeter works artificial walls are provided between the filters, but in any case where the site admits of these being dispensed with under the Sutton system, they could equally well be done without under ours."	(4) In the cost given above for filters at Sutton, artificial walls are included. The fine-grain or coke-breeze filters are essentially the same in both systems (Mr. Cameron having copied his from those at present in use at Sutton and Barking, as admitted by him in the printed copy of his evidence at the Exeter inquiry), so that the cost should be the same under similar circumstances, with this exception, that the cost of patent alternating gear will be an extra to add to the cost under the Exeter system.
(5) "Although the walls and floors do not represent by any means the heaviest part of the cost of the filters, their omission would reduce to some extent the excess of this item over the cost of the tanks. Against this must be set the possibility of reducing the cost of the tanks under other circumstances—for instance, those under consideration are larger than they would be in some cases for the same population."	(5) In no case under the Exeter system could artificial tank walls, floor, or roof be omitted, as is possible with the Sutton system. The cost of these under any circumstances must always be heavy. The suggestion as to the possibility of reducing the cost of tanks where no provision is made for storm-water is valueless when the relative costs are based on the cost of works for treating 100,000 gallons per day in each case.
(6) "The fall required is often an important factor in the cost of works. The Exeter system requires only one-half the fall necessary for the Sutton system."	(6) The Sutton system may be adopted where there is only 2ft. of available fall, so that such an objection as that raised is of no practical utility.
(7) "The '(Septic)' tank deals with the sewage without preliminary screening, thus saving the cost of clearing the screens and disposing of the intercepted matters."	(7) Any item of cost of labour in attending to filters, either in large works laid out on the Sutton system or small works, must be of necessity small, as in the former automatic screens, and in the latter duplicate screens would be provided, requiring attention once or twice per day for a few minutes. Under the Exeter system grit chambers are necessary, which, as has been shown by the evidence at the Local Government Board inquiry and in the correspondence between Mr. A. J. Martin and Mr. Somerville, will require emptying probably two or three times a year, and also that the tanks themselves will require emptying. The cost of removal and disposal of the insoluble deposit in the grit chamber and the tank will be a serious one, and counterbalance the cost of screening, &c., in the Sutton process, which is extremely small. Moreover, it appears that in very small works the tanks must be in duplicate to provide for the flow of one while another is being freed from insoluble deposit.
(8) "Secondly, they do not require the periodical trenching which is necessary for the coarse bacteria bed."	(8) The small amount of labour (only required once per week at the outside), which consists in raking or forking over the surface of the filter, entails practically no extra cost, as it is performed by the man attending to the valves. The same attention is required to the fine-grain filters in the Exeter process, which your correspondents appear to have omitted to state.
(9) Thirdly, the automatic alternating gear saves the labour which would otherwise be required to work the filters, and what is of greater importance prevents the temporary losses of their purifying power, which negligence on the part of the attendants is liable to bring about.	(9) The alternating gear, which probably is the main validity of the company's patent, is ingenious and noteworthy. Whether the cost of this will be compensated by the assumed saving in labour and regularity of working, time alone will prove. It has yet to be discovered, however, that artificial filters can be treated as automatic machines. Experience has shown, on the other hand, the opposite. Sewage varies in character from hour to hour during the day, when it is generally strong, while during the night it is of a weak character. If it be intended to give a strong sewage or effluent, the same period of contact with the filters as a weak sewage, failure will result. Moreover, during the period of maximum flow of the day sewage, when generally it is the strongest, the discharge from the septic tank will increase, and the filters will have to work faster, as the cycle of time will be shortened owing to the increased flow; hence the action of the alternating gear on the filters may be detrimental. That constancy in working of the filter which is claimed to be gained by the use of the automatic gear, may be productive of very variable effluents, and result in condemnation of the system of biological purification.
	One other objection to the alternating gear, which it is desirable should not be

A	B
	overlooked, is that the discharge valve is opened its full diameter at the commencement, when the filtrate is liberated with a rush, carrying with it the fine material and fouling the filtrate.
(10) "If the annual saving which our system effects, even as compared with that of Sutton's, is capitalised, we venture to think it will dispel any doubt which might otherwise exist as to the relative cost of the two systems."	(10) The Exeter system cannot be adopted under the existing rules of the Local Government Board unless land is also provided. This will require that a man be in attendance to cultivate it, even in small works, and it is therefore doubtful whether under such circumstances any saving is to be effected in labour by the alternating gear over that of ordinary valves as in the Sutton system. The latter process may, however, and is already, I believe, adopted in some districts of small population, where attendance to the filters can be reduced to the brief time of half an hour or so per day.
	It has been shown that the capital cost of works under the Exeter system is very considerably above the Sutton system, and that the statement of the patentees in paragraph 3 is incorrect. Similarly the cost of working will, in any event, equal that of Sutton, although each is comparatively small.

There are many other points which may be urged in friendly criticism of the Exeter process, and the same may equally well be said of the Sutton process, but, after all, they are small as compared with the glaring defects in the old and costly precipitation processes hitherto chiefly in vogue. Whether the Exeter or the Sutton process appeals to engineers and Local Authorities as the more satisfactory is unimportant to the adherents of the latter system. Each, however, will be found to be a long way ahead, it may be confidently stated, of any hitherto known process of sewage treatment.

In conclusion, I must apologise for the undue length of this letter, and also express my personal regret that Messrs. Cameron, Commin, and Martin's letter should have necessitated a reply from me, and cause me to assume an apparently antagonistic position which is not intended.—Yours truly,

C. CHAMBERS SMITH,
Engineer and Surveyor to the Urban District Council.

Sutton, Surrey, February 23rd, 1898.

AT a meeting of the Matlock Town Council on Monday Sir George Newnes, Bart., presented the undertaking known as the Matlock Cable Tramway Company to the town, which is situated in his native district. The gift was unanimously accepted, and is worth £20,000. There will be a public recognition of Sir George's generosity.

Notes and Queries.

987.—CUBICAL CAPACITY OF TANKS &c.: BOOK ON.—"E D. G." writes:—"Could you recommend me a reliable book from which I could learn how to calculate the capacity of pipes, tanks, rooms, &c., as I know very little of arithmetic? I want one that will thoroughly explain the working out of such problems."

Answer.—The following books are recommended for the purpose required:—(1) Clarke's "Calculations of Cubic Space," post free, 1s. 0½d. (2) Maxwell's "Calculation of Areas, Cubic Space, &c.," price 2s. Either of the books may be obtained from The Sanitary Publishing Company.

988.—MICA-FLAP VALVES: HOW OBTAINABLE.—"Subscriber" writes:—Will you please inform me of the names of makers of the Mica-flap valves, also say whether the mica can be purchased separately?"

Answer.—Mica-flap valves are manufactured by Messrs. Young and Marten, Caledonian Works, Stratford, London, E.; Messrs. J. Mitchell and Co., Drury-lane, London; and Messrs. Sankey and Son, Canning Town, London, E., from whom, no doubt, mica can also be purchased separately if required.

989.—TOWN: WHAT CONSTITUTES A.—"Surveyor" writes:—"A place with 5000 inhabitants has just been given urban powers which come into force on March 25th, when it will become an urban district. Can the Surveyor be described as Town Surveyor, and what constitutes a town?"

Answer.—The term "town" is one which is used in a general sense, and cannot absolutely be defined. Usage has associated it with any collection of houses larger than a village, and when the place has a population of several thousands. Urban districts are generally described as towns. There is nothing to prevent the Surveyor of an Urban Authority describing himself as "Town Surveyor" if he desires to do so.

990.—PUMPS: FILTRATION OF WATER: BOOKS ON.—"G. G. B." writes:—"I am in want of a cheap and practical work on (1) pumps, also (2) one treating on the collection and filtration of water on a small scale. Will you kindly recommend suitable books?"

Answer.—The following books will be found to meet the requirements of our correspondent, viz.:—(1) Pumps: "A Practical Handbook on Pump Construction," by P. R. Björling, price 5s. (2) Water supply: "Rural Water Supply," by Greenwell and Curry, price 5s. The latter book contains a chapter on the filtration of water and the construction of filter-beds. Either of the books may be obtained from the Sanitary Publishing Company.

991.—DWELLING-HOUSES REQUIRING LIME-WASHING: PROCEDURE.—"A. B." writes.—"In going my rounds I have noticed several houses in various parts of the district which require lime-washing. I should be glad if you would kindly advise me what steps I ought to take as a Sanitary Inspector with a view to getting the work done as regards cleansing the houses in question. In the event of your deciding that I ought to deal with them under the head of a nuisance, ought I to serve the notice on the owner or occupier, and further, whether the owner or occupier is responsible?"

Answer.—If the dwelling-house be in such a state as to be a nuisance or injurious to health, within the definition in Sec. 91 of the Public Health Act, 1875, the Local Authority, if satisfied of the existence of a nuisance, may serve a notice on the person by whose act, default, or sufferance the nuisance arises, and in this case the notice should be served on the occupier. Proceedings in the alternative may be taken under the provisions of Sec. 120 of the Act of 1875, if the Medical Officer of

Health or any other legally qualified medical practitioner furnishes the Local Authority with a certificate that the cleansing and disinfecting of any house or part thereof, &c., would tend to prevent or check infectious disease. Where, however, the Infectious Disease (Prevention) Act, 1890, has been adopted, proceedings would have to be taken under Sec. 5 of this Act, as it repeals Sec. 120 of the Act of 1875.

992. — MEMBER OF DISTRICT COUNCIL INTERESTED IN CONTRACT: DISQUALIFICATION.—"H. T." writes:—"If a member of an Urban or a Rural District Council supplies or conveys goods to a contractor who is doing work or conveying goods for such contractor on behalf of either of these Councils, is such illegal, and what is the forfeit, if any?"

Answer.—By Sec. 46 of the Local Government Act, 1894, a person shall be disqualified for being elected or being a member or chairman of a Council of a parish or of a district other than a borough or Board of Guardians, if he is concerned in any bargain or contract entered into with the Council or Board, or participates in the profit of any such bargain or contract or of any work done under the authority of the Council or Board. It is also provided by the same section that if a member becomes disqualified for holding office, &c., the Council shall forthwith declare the office to be vacant, and that if any person acts when disqualified or votes when prohibited, under this section he shall for each offence be liable on summary conviction to a fine not exceeding twenty pounds. The provisions, as aforesaid, apply to members of Urban or Rural District Councils, and in the case named by our correspondent the member will be disqualified, and the Council are required to declare the seat vacant. He will also be liable to the penalty if he acts as a member while interested in the contract.

993.—DEFECTIVE DRAINAGE: PROCEDURE TO ENFORCE REMEDY.—"J. W." writes.—"An untrapped, unventilated, and defective drain is reported to an Urban Authority by their Inspector of Nuisances, who is thereupon ordered to serve the necessary notices. Should notice be served under Sec. 94 or Sec. 23? If served under Sec. 23 and not complied with, can the Urban Authority carry out the work and recover the cost?"

Answer.—The Local Authority have the option as to whether they will proceed under Sec. 23 or under Secs. 91-96, but there is this difference in the cases, that the course prescribed by Sec. 23 is remedial, while that under Secs. 91-6 is punitive. In the former case the object is to remedy the defective accommodation as soon as possible, and it is, as a rule, the most satisfactory course to take, while the object of Secs. 91-96 is to punish the owner for suffering defective drainage, amounting to a nuisance, to be in existence, and to seek its abatement. In the event of the owner not complying with the notice under Sec. 23 within the specified time, the Authority may do the work required, and may recover in a summary manner the expenses incurred by them in so doing from the owner, or may, by order, declare the same to be private improvement expenses.

Vacancies.

ASSISTANT ENGINEER (LONDON, E.C., March 21st).—For the Bengal-Nagpur Railway Company, Ltd. Salary, first year, Rs.450 per mensem; second year, Rs.500 per mensem; third year, Rs.550 per mensem. Mr. Robert Miller, managing director, 132, Gresham House, Old Broad-street, London, E.C.

ASSISTANT MANAGER (March 14th).—For gas works near London. Gas Company, 1, Cullum-street, London, E.C.

ELECTRICAL ENGINEER, &C. (MANCHESTER, March 14th).—Committee, Co-operative Wholesale Society, Ltd., 1, Balloon-street, Manchester.

ENGINEER (RUSKINGTON, March 12th).—For the Urban District Council. Mr. James Adlard, clerk, Ruskington, Sleaford.

ENGINEER AND MANAGER (HINCKLEY, March 21st).—For the Urban District Council. Salary not to exceed £250 per annum, with house, coal, and gas. Mr. J. W. Preston, clerk, Hinckley.

ENGINEERING ASSISTANT (WEST HARTLEPOOL, March 29th). Salary, £2 per week. Chairman of the Works Committee, Borough Engineer's Office.

INSPECTOR OF NUISANCES (PUDSEY, March 14th).—For the Urban District Council. Salary, £80. Mr. Benjamin Dufton, clerk, Council-offices, Pudsey.

INSPECTOR OF WEIGHTS AND MEASURES, &C. (HASTINGS, March 11th).—For the Corporation. Salary, £90 per annum, rising by annual increments of £5 to £125 per annum, and in respect to each of the other offices £5 per annum. Mr. Ben F. Matthews, town clerk, Town Hall, Hastings.

INSPECTOR OF NUISANCES, SURVEYOR, &C. (WINDERMERE, March 16th).—For the Urban District Council. Salary, £100 per annum. Mr. J. T. Bownass, clerk, Windermere.

SURVEYOR (DOUGLAS, ISLE OF MAN, March 23rd).—For the Town Council.—Salary, £200 per annum. Mr. Thomas S. Nesbitt, town clerk, Town Hall, Douglas.

SURVEYOR (NEWHAVEN, March 14th).—Salary to commence at £90 per annum. Mr. Edward Knightley, clerk, Council Chamber, Newhaven, Sussex.

WATERWORKS MANAGER (FAVERSHAM, March 16th).—For the Faversham Water Company, Ltd. Salary, £80 per annum. The Secretary's Office, 50, Preston-street, Faversham.

ANTISEPTIC

DISINFECTANT. DEODORANT.

INODOROUS DISINFECTION.

Absolutely Non-Poisonous, Non-Corrosive, Non-Volatile, and does not Stain.

See published Bacteriological Report by Dr. E. KLEIN, St. Bartholomew's Hospital, London.

CHINOSOL SANITARY TABLETS are the most convenient, most effective, and most economic for the immediate production of Disinfecting Fluids. **12 Tablets**, packed in one tin to carry in waistcoat pocket, price **2s.** One Tablet in warm or cold water produces in **less than one minute**:—

3 Quarts of a strong Deodorant and Disinfectant, sufficient to spray one infected room of 1000 cubic feet; or
3 Gallons of a strong Disinfectant for flushing drains, walls, floors, &c.

Literature (Dr. Klein's Report) and Samples free to the Profession.

B. KUHN, 36, ST. MARY-AT-HILL, LONDON.

Telegraphic Address: 'CARMINES, LONDON. Telephone: Avenue 5976.

Contracts Open.

The dates given below are the latest up to which tenders can be received.

SURBITON. — March 14th. — Sewer, &c. — Surveyor, Council Offices, Victoria-road, Surbiton.

TIPPERARY (IRELAND). — March 14th. — Sanitary Works. — Mr. Joseph Gubbins, clerk, Workhouse, Tipperary.

WALSALL.—March 14th.—Scavenging.—Mr. A. H. Lewis, clerk, 1, Leicester-street, Walsall.

LONDON, W.C. — March 15th. — Sewers, &c. — 197, High Holborn, W.C.

SHOEBURYNESS.—March 15th.—Sewers.—Mr. Harold Harris, Clarence-street, Southend-on-Sea.

BROWNHILLS (STAFFS).—March 16th.—Removal of Nightsoil.—Mr. J. H. Shaw, surveyor, Council Offices, Brownhills.

MANCHESTER. — March 16th. — House Drainage Works. — The City Surveyor's Office, Town Hall, Manchester.

PLUMSTEAD. — March 16th. — Sewers. — Mr. W. C. Gow, C.E., surveyor to the Vestry, Maxey-road, Plumstead.

LONDON, N.W. — March 17th. — Sewers, &c. — Mr. James A. Webb, engineer to the Council, Great Stanmore, Middlesex.

GOWERTON (NEAR SWANSEA).—March 19th.—Drain, &c.—Mr. J. Thomas, A.M.I.C.E., surveyor and engineer to the Council, 32, Fisher-street, Swansea.

STAFFORD.—March 21st.—Drain and Sewer Pipes.—Mr. W. Blackshaw, borough engineer, Borough Hall, Stafford.

COMPETITIONS.

WINCHESTER, March 31st.—Public Baths. Extension of Time.—The time for submitting plans for the public baths competition is extended to March 31st. Premiums of £25 and £15 will be awarded for the designs adjudged by the Council of sufficient merit, and placed first and second in order respectively. The premiated plans will become the property of the Corporation. Drawings and detailed estimate to be deposited at the office of Mr. Walter Bailey, town clerk, Guildhall, Winchester, marked "Swimming Baths," on or before March 31st, instead of 28th inst., as previously mentioned.

To Surveyors, Sanitary Inspectors, &c.—First-class Cycles at reasonable prices. Don't place your orders elsewhere until you have seen our post-free catalogue.—MELROSE CYCLE COMPANY, Coventry.

INSURANCE.

THE MUTUAL LIFE INSURANCE COMPANY OF NEW YORK.

PRESIDENT:
RICHARD A. McCURDY.

Policy-holders in the "Mutual" enjoy the advantages of

SCHERING'S NEW DIETETIC.

This is a new albumen preparation for domestic use. Its constituents, similar to milk, especially Human Milk, give it a peculiar value.

SANOSE

SANOSE is an odourless and tasteless white powder, forming an emulsion when stirred in water.
THE MEDICAL PROFESSION strongly recommends it in cases of Anæmia, Dyspeptic troubles, Consumption, and in Cachectic Women.

For literature see "THE THERAPIST," November, 1897, and January, 1898.

Price 1s. per ounce; 3s. 6d. per 4 ounces.

Apply to all Chemists and Druggists, or to **A. & M. ZIMMERMANN, 9-10, St. Mary-at-Hill, London. E.C.**

SITUATIONS.

VACANT.

☞ *Advertisements of Situations Vacant are inserted at the rate of Sixpence per line (prepaid), minimum three lines — eight words to line. Special rates for a series.*

WANTED.

THE SANITARY RECORD *will be found an excellent medium for those who are desirous of seeking Situations in the Offices of Surveyors, Sanitary Inspectors, Sanitary Engineers, Architects, &c. The charge for such advertisements (prepaid) is Sixpence per line. Minimum three lines—eight words to the line.*

☞ **Advertisements for this Department must reach us by Tuesday morning in each week, at latest.**

SANITARY INSTITUTE EXAMINATIONS.

TUITION BY CORRESPONDENCE.

An Engineer and Surveyor (Mem. San. Inst.), Certificated Surveyor and Inspector, prepares students for these Exams. by Correspondence through the post.

Fees strictly moderate. Cramming studiously avoided.

The course of tuition is arranged so as not only to qualify the student for passing the exams., but what is of equal importance, viz., that he may become a thoroughly efficient Inspector.

On successfully passing the exams., all possible assistance and advice is given to help forward intending candidates for public offices.

Many of my old pupils are now filling positions with salaries of over £120 a year.

For terms, &c., address "C. E.," care SANITARY RECORD, 5, Fetter-lane, London, E.C.

SANITARY ASSOCIATION OF SCOTLAND.

EXAMINATIONS IN SANITARY SCIENCE.

Examinations for Certificates of Competency in Sanitary Science are held each year as follows, viz.:—In Glasgow in April, in Edinburgh in October, and at such other time and place as the Board of Examiners may determine.

Entrance Fee £2 2s.

For further particulars apply to

GEORGE MIDDLETON, M.A., LL.B.,
Writer, 92, Bath Street, Glasgow,
Secretary to the Board of Examiners.

A Stamped Addressed Envelope must accompany all letters requiring an answer.

SANITARY INSTITUTE EXAMINATIONS.

SPECIAL Corresponding Classes for the **Practical Sanitary Science,** and **Sanitary Inspectors' Examinations** of the **Sanitary Institute, 1898,** conducted by a gentleman holding appointments as Urban District Council Engineer and Sanitary Inspector, holder of three certificates from the Sanitary Institute, First-class Honour Medallist Hygiene, &c. Hundreds of successes.—For all particulars, testimonials, &c., apply Mem. San. Inst., Office of THE SANITARY RECORD, 5, Fetter-lane, London E.C.

OFFICIAL ADVERTISEMENT.

COUNTY BOROUGH OF NORTHAMPTON.

WANTED at once, an additional INSPECTOR of NUISANCES.

Salary £100 per annum, and uniform.

Candidates must have had experience in the duties of an Inspector and hold the certificate of the Sanitary Institute.

Applications, together with copies of not more than three recent testimonials, to be sent to me on or before Monday, the 21st March instant.

THE DRAINAGE OF VILLAGES.

BY

WILLIAM SPINKS, Assoc. M. Inst. C.E.,

Member of the Incorporated Association of Municipal and County Engineers; Member of Sanitary Institute Lecturer on Sanitary Engineering—Yorkshire College—Victoria University; President of Sanitary Engineering Section of the British Institute of Public Health, 1895.

SYNOPSIS OF CONTENTS.

PART I.—Statutory Powers—Pollution of Streams—In case of Failure to Provide Schemes—Existing Sewers—Present Means of Disposal—Composition of Sewage—Self-purifying Power of Rivers.

PART II.—Areas of District to be Sewered—Power to enter Private Lands—Works without District—Special Drainage Districts—Power to Agree with neighbouring Authority to take and deal with Sewage—Joint Sewerage Boards—Rainfall—The Geological Character of the District—Present and Prospective Number of Inhabitants—Supply of Water—Sanitary Appliances—Position of Outfall Works—Power to Purchase Lands—Borrowing Powers.

PART III.—Requirements of a Sewerage System—Depths—Gradients—Lines—Sewers and their Jointing—Manholes—Flushing—Ventilation.

PART IV.—Sewage Disposal—Purification through Land—Tanks—Sludge—Filtration.

The SANITARY PUBLISHING COMPANY, LTD., 5, Fetter Lane, LONDON, E.C.

Price 2s. 6d.; by Post, 2s. 9d.

A HEALTHY HOME.

By FRANCIS VACHER, F.R.C.S., M.R.C.P., M.O.H., Cheshire.

CONTENTS.

CHAPTER I.—**Introductory:**—Health of the Individual and Family—How shall they be Housed Wholesomely?

CHAPTER II.—**Site. Soil. Aspect:**—Desiderata as regards Site—Constituents of Soil—Ground Water—Rainfall—Diseases connected with Ground Water.

CHAPTER III.—**Building Materials.**

CHAPTER IV.—**Construction:**—Foundation—Walls—Damp Course—Damp-proof Coating—Thickness of Walls—Size of Floor Joists—Drain Pipes and Gutters—Height of Chimneys.

CHAPTER V.—**Design and General Arrangements.**

CHAPTER VI.—**Warming: Lighting and Ventilation.**

CHAPTER VII.—**Hot and Cold Water:**—Source of Supply—Pollution in Transit—Cisterns—Filtering—Service Pipes.

CHAPTER VIII.—**Sanitary Requisites:**—Drainage—House Drains—Drain Testing—Disconnecting from Sewers—Soil Pipe—Closets—Baths—Sinks—Grease and Gulley Traps.

CHAPTER IX.—**Decoration and Furniture.**

CHAPTER X.—**Stables, Cowsheds, &c.:**—Lighting and Ventilation—Drainage—Space required for each Cow.

CHAPTER XI.—**House Cleaning.**

CHAPTER XII.—**Obligations of Householder and Sanitary Authority:**—Right of Drainage into Public Sewers—Examination of Drains—Removal of Filth—Abatement of Nuisances.

IMPORTANT ANNOUNCEMENTS.

WILL SHORTLY APPEAR IN THE

Sanitary Record

A SERIES OF ARTICLES

ENTITLED—

"THE CHEMICAL AND BIOLOGICAL EXAMINATION OF WATER,"

BY

C. G. MOOR, M.A., F.C.S.

These Articles, which have been expecially written for THE SANITARY RECORD by Mr. Moor, will be fully illustrated, and will embody the results of the latest researches on this all-important subject.

The writer holds a unique reputation as joint author (with Mr. T. H. Pearmain) of "Applied Bacteriology" and "Aids to the Study of Bacteriology," both of which works have received high encomiums from the *Lancet*, the *British Medical Journal*, the *Chemical News*, &c., and we have no hesitation in commending this new series to the notice of all Public Bodies who are interested in the purity of public water supplies.

A

New Series of Articles

BY

W. J. DIBDIN, F.I.C., F.C.S.,

Late Chemist to the London County Council, Author of "The Purification of Sewage and Water," &c.,

WILL COMMENCE IN

The Sanitary Record

AT AN EARLY DATE.

Mr. Dibdin has chosen for his subject—

"LIME MORTAR AND CEMENT: Their Composition and Analysis,"

And the Articles will prove invaluable to Surveyors, Municipal Engineers, &c.

The date of publication will be duly announced in this column.

NOTICES.

ANNUAL SUBSCRIPTIONS. — The Annual Subscription to "The Sanitary Record," paid in advance, is 10*s. This includes postage, and a Copy of the Diary, post free.*

SUBSCRIBERS RESIDING in SCOTLAND and IRELAND are requested to pay by P.O. and NOT *by cheque. If cheques* BE *sent they must be drawn for* 10*s.* 6*d*

MSS. cannot be returned unless accompanied by a stamped directed envelope.

Advertisements cannot be inserted unless received before Four o'clock on the TUESDAY of each week.

All communications should be addressed to the EDITOR, at 5, *FETTER LANE, London, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, Ld.*

THE

Sanitary Record,

MARCH 18, 1898.

Notes.

The Plague in India.

THE latest news regarding the plague in India is of the very gravest character. In the first place, as regards the ravages of the epidemic, it is exceedingly distressing to learn that so far from there being any diminution in the

number of deaths, the mortality is alarmingly on the increase. The deaths from plague during the week ending 10th March amounted to 1283, being an increase of 16·95 per cent. on the figures for the preceding week, which were 1097. The number of deaths from all causes was 2184 during the week, representing a death-rate of 136·36 per 1000, as compared with a mortality of 2080, representing a death-rate of 129·98 per 1000 during the previous week. These figures alone are sufficient to cause the gravest anxiety, but an additional ground for anxiety is provided by a telegram which announces that a new outbreak, apparently of a different description, and called the "black blister," has broken out in the Nizam's dominions, and is causing fifty deaths a day.

The Friction with the Corporation.

As if the already over-burdened Government were not sufficiently harassed by this new and alarming spread of the disease, their efforts have been further hampered, first by a most unfortunate friction with the Corporation of Bombay, and second by a very serious renewal of rioting, arising out of the native discontent with the preventive measures enforced by the Plague Committee. The Plague Committee has been spending two and a-half lakhs of rupees monthly. A steady supply of money is absolutely necessary to carry on the work, but the Corporation, in pursuance of some fatuous policy of opposition, suddenly stopped the supplies. Cheques for 38,000 rupees had been issued, to meet which there were only 4800 rupees in the bank. In this emergency Sir James Campbell, with praiseworthy promptitude, arranged with the bank for an overdraft of half a lakh of rupees on his own personal security to meet the contingencies, and thus the crisis was temporarily tided over.

The Riots.

The troubles of the Government culminated, as we have said, in a serious native riot on the 9th inst. The disturbances originated in connection with the attempted removal of a Mohammedan female plague patient to hospital. A mob collected and assumed so menacing an attitude that the police were compelled to fire, a step which had the effect of dispersing the mob for the time. They subsequently, however, reassembled and attacked one of the hospitals, and indulged also in promiscuous rioting in various quarters of the town, attacking and ill-treating isolated Europeans wherever possible. The military was promptly called out, and suppressed the disturbance, but not before a number of lamentable casualities had taken place, including two British soldiers, who were killed, though they had not been engaged in plague inspection, and several police officers, a Parsee magistrate, and a nurse, who sustained injuries more or less severe. A few of the rioters were killed, a number were injured, and a large number of arrests were made. By means of vigorous patrolling of the streets, quiet was eventually restored—at least for the time.

The Causes of the Disturbances.

Lord George Hamilton stated in the House of Commons, on receipt of this disquieting news, that he was confident that the disturbances were not due to any excessive or unnecessary severity in the enforcement of the sanitary regulations. Every effort is being made by the Government to avoid irritating the religious susceptibilities of the natives, and with this object they are endeavouring to secure the co-operation of native gentlemen of position and influence in their humanitarian work. But notwithstanding this, there is no blinking the fact that the operations of the search parties, however decorously conducted, the quarantine rules, and especially the regulations for death registration, wound the religious feelings not only of the Hindoos, but also of the Mohammedans. So deep is the feeling of irritation that the shopkeepers of both sections of the people have closed their premises, by way of protest against the plague measures, and about 15,000 dock labourers and carters have gone out on strike. The result threatens to be commercial panic, and may have serious consequences. In view of the bitter feeling throughout the city, the Plague Committee can hardly prosecute their labours without providing adequate protection for the search parties in the work of visitation. It is, in truth, a hard and a thankless task which the Government of Bombay have before them, when their efforts to save the devoted city from ruin meet with nothing but blind prejudice and bitter hostility.

The Small-pox at Middlesbrough.

It is a relief to turn from this black picture of sanitary administration abroad to a brighter state of affairs at home. We are thankful to hear that the epidemic of small-pox at Middlesbrough is abating, though the Sanitary Authorities are hardly yet in a position to relax their efforts. The number of cases notified last week showed a steady and most gratifying decline from day to day. From nineteen in one day in the beginning of the week, the number of fresh cases fell on Thursday to eleven, and on Friday to only eight, five, however, being from houses previously free from infection. All the cases were promptly removed to hospital. Two of the latest sufferers were workmen from London, who were engaged in constructing the temporary corrugated iron hospitals, and one of them succumbed. The outlook is, however, now much brighter. The epidemic is evidently dying down, and the Authorities, whose energy in coping with the malady has been most praiseworthy, are to be congratulated on the prospect of soon being able to see the town completely freed from the disease.

Food and Drugs Adulteration.

On Friday last a deputation from the Federation of the Grocers' Associations of the United Kingdom, claiming to represent 150,000 shopkeepers in the provision trade, waited on Mr. Chaplin, President of the Local Government Board, to urge upon the Government the desirability of bringing in at the earliest possible opportunity a Bill to amend and consolidate the Sale of Foods and Drugs Acts, 1875 and 1879, and the Margarine Act 1887, on the lines of the recommendations contained in the report of the Select Committee on Food Adulteration published in 1896. In urging their point, the deputation made it clear that, so far from having any objection to the principle of the laws in pre-

vention of adulteration, they wished to see them strengthened and enlarged.

Lack of Unanimity in the Trade.

Mr. Chaplin, in his reply, promised to give his closest attention to the various questions pressed upon his notice, but at the same time pointed out that one of his greatest difficulties in formulating legislation lay in the fact that not only had there been considerable difference of opinion in the Parliamentary Committee, but in the trade itself unanimity was still far from being attained. One of the points to which the Committee attached almost more importance than to anything else was the provision whereby they recommended that the colouring of margarine and the mixing of margarine and butter should be altogether prohibited, and to this provision many of the members of the Federation offered strong objections. Another question discussed in the memorial of the Federation was the constitution of the Court of Reference, and in dealing with this Mr. Chaplin dwelt upon the difficulties in determining the scope and character of the proposed Court. All these matters, as well as the questions of invoice warranty, more efficient inspection, and greater uniformity in prosecutions, would, he said, require anxious consideration.

Public Health in Glasgow University.

The advocates of the institution of a separate Chair of Public Health in the University of Glasgow have not so far succeeded in attaining their object. The subjects of forensic medicine and public health, which have hitherto been taught by one professor, are to continue to be so associated, and the chair rendered vacant by the retiral of Professor Simpson has been filled by the appointment of Dr. John Glaister. Though it is a matter for regret that the opportunity to separate the two subjects has not been utilised, and the establishment of a chair for the exclusive treatment of public health, which must come some day, has in the meantime been deferred, we are glad to see that the present appointment has been conferred on so able an exponent of hygiene as Professor Glaister. He is a Diplomate in Public Health of Cambridge; he has for a number of years taught hygiene as well as medical jurisprudence in St. Mungo's College, in which institution he has had a sanitary science laboratory for some time under his direction; he has for several years been examiner in public health, as a special subject for study and examination for the Royal Colleges of Physicians and Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow; he is a Fellow and Member of Council of the Royal Institute of Public Health, and a Member of the Council of the Sanitary Association of Scotland; and he has made his mark in the literature of sanitation. With such a list of qualifications, in addition to others of a like nature to which we have not referred, sanitarians will feel well satisfied that Professor Glaister will give due prominence to the public health side of his chair. We heartily congratulate him on his appointment.

Influenza in Parliament.

The frequent mention in the columns of the daily Press of the prostration of many members of Parliament through the prevailing scourge of influenza, has given rise to an impression in the public mind that an unusual proportion of our legislators have been the victims of the fashionable malady. This impression is happily unfounded. As a matter of fact, influenza has not been more rife in Parliament than it has been elsewhere, and the number of members of the House of Commons who have been laid aside is comparatively small. Owing to the eminent position of some of the sufferers, among whom falls to be included the Prime Minister, the public have not been slow to note the existence of the epidemic in Westminster, and have formed greatly exaggerated notions as to its extent. Dr. Farquharson, who as a medical member is well qualified to speak, has stated that the House of Commons is well ventilated, and the general conditions of the House are on the whole so healthy and well arranged that members are not likely to become victims in exceptional numbers to an epidemic.

Unsound Meat Destroyed Without Justices' Order.

The case of Ormerod *v.* Mayor, Aldermen, and Burgesses of Rochdale, decided at the Manchester Assizes on February 11th, is one which should be of considerable utility to Officers of Health. The action was brought by a butcher against the Corporation named, to recover damages for the improper destruction of meat belonging to the plaintiff by the Medical Officer of Health and the Assistant-Inspector of Nuisances, the latter of whom, acting under the directions of the Medical Officer, seized a quantity of meat exposed in the plaintiff's shop, which appeared to be unfit for the food of man, and destroyed it without having first obtained an order of justices, as required by Sec. 117 of the Public Health Act, 1875. It was contended for the defendants that the meat was unfit for food, and that the plaintiff assented to its being destroyed; and further, assuming the meat was good, the Medical Officer of Health and Assistant-Inspector of Nuisances were not the servants of the defendants in seizing and destroying the meat, nor did they seize or destroy by the orders and directions of the defendants. The jury found a verdict for the plaintiff, and assessed the damage at £50. It was held by Bruce, J., that the two officers were the servants of the Corporation, that they were acting within the scope of their duties as such, and that they neglected to take the proper steps to have the meat condemned by a justice, as required by Sec. 117 of the Act of 1875, and for these reasons he gave judgment in accordance with the verdict of the jury. The case is one which shows the necessity of Officers of Health proceeding strictly within the provisions of the Act, and how an omission in procedure may involve Local Authorities in unfortunate consequences.

Wigan.—Mr. G. Heaton, surveyor, is preparing a scheme for laying water-pipes from the boundary of Upholland to Finch-lane, Wrightington, in order to proceed with the work at once.

NOTES ON PRACTICAL SANITARY SCIENCE.

By WILLIAM H. MAXWELL.

Assistant Engineer and Surveyor, Leyton Urban District Council, Author of "Drainage Work and Sanitary Fittings," "Ventilation, Heating, and Lighting," &c., Certificates of the Association of Municipal and County Engineers, and Sanitary Institute.

No. 53.—REFUSE DESTRUCTORS.

(*Continued from page* 252.)

BEAMAN AND DEAS' DESTRUCTOR.

In addition to the towns named on p. 249—March 11th—it should have been mentioned that the Corporations of Canterbury, Cardiff, and Sheffield (10 cells), and the Llandudno Urban District Council have also determined upon the erection of the Beaman and Deas' furnace.

As regards the capacity of this type of destructor it has been found capable of dealing with 24 tons of house refuse per cell per 24 hours, whilst the *average* consumption of the furnaces named in the accompanying table (compiled in 1892 by Mr. G. Watson) will be seen to be 6·3 tons per cell per 24 hours.

The table is as follows :—

Name of town.	Number of cells.	Make of cells.	Average tons burnt per day of 24 hours.	Equal to tons per cell per 24 hours.	Cost of burning per ton. Returns deducted in each case.
					s. d.
Battersea	12	Fryer's	8 1¾	6·81	2 2½
Bradford	24	Fryer's, fitted with Horsfall's steam jet	170	7·09	1 5
Ealing...	4	Fryer's	20	5·00	0 4½
Hornsey	6	Warner's	35	5·83	0 10¼
Leeds	Burmantofts, 14	Fryer's, fitted with Horsfall's steam jet	216	6·00	1 7¼
	Armley-road, 12	Do. do. do. do.		6·00	
	Kidacre-street, 10	Combination of Fryer's and Horsfall's		6·00	
Leicester	6	Fryer's, with Biddle's patent grate bars	33	5·50	1 3
Newcastle-on-Tyne	6	Warner's	48	8·00	1 0¼
Southampton	6	Fryer's	50	8·33	Profit 2¾
Bolton	8	,,	50	6·25	0 2½
Bury	4	,,	20	5·00	1 10½
Liverpool	12	,,	96	8·00	1 3
Salford	6	,,	28	4·66	1 6
Whitechapel	8	,,	60	7·50	2 3
Oldham	6	Horsfall's	37½	6·25	1 1

Assuming the consumption of a Beaman and Deas cell at the rate of 24 tons of unscreened refuse per 24 hours, and an average water evaporation of 1 lb. per pound of refuse[136], the theoretical value of a cell in indicated horse-power, supposing an engine to consume 20 lb. of steam per indicated horse-power per hour, would be :—

$$\frac{2240}{20} \text{ (pounds of water evaporated per hour)} =$$

112 indicated horse-power continuously all the time of working.

At the Leyton installation of the Beaman and Deas destructor (which has been built not only for the cremation of house refuse, but also for the disposal of pressed sewage sludge cake from the Leyton Sewage Works), many tests have been made by various public authorities in the burning of house refuse, slaughter-house offal, market vegetable refuse, &c., of which the following are some of the particulars :—

St. Pancras Vestry Test at Leyton.—On the morning of May 11th, 1897, a consignment of refuse amounting to 18 tons 13 cwt. 3 qr. was taken down to Leyton by the Vestry's contractor for the collection of house refuse. The charging of the first cell commenced at 7.30 a.m., and that cell continued at work until 7.20 p.m., having destroyed in that time eight charges. The work on the other cell was commenced at 7.55 a.m., and continued to 9.15 p.m. This cell also destroyed eight charges.

The average time the fires were at work was therefore 12 hours and 40 minutes, during which time 16 tons 13 cwt. 3 qr. were consumed, being at the rate of 15·8 tons per cell per day of 24 hours. It should, however, be stated that owing to a mistake in placing too heavy a final charge in the second cell, a considerable delay occurred, otherwise the quantity burned per cell would have been higher.

Two men only were needed for the work, and charging their rate of pay at the same as is paid by the Vestry, viz., 6½d. per hour, the cost of burning the refuse was 9¾d. per ton.

The rate of temperature throughout the test was very high indeed, beyond the range of the ordinary test, probably between 2000 and 2500 deg. Fah., and with such a temperature there was, of course, no difficulty in keeping up the steam pressure in the boiler. In fact, the hot air had to be passed through the bye-pass flue, as the boiler commenced blowing off steam one hour after the commencement of the test.

The test was carried out in the presence of the Vestry's engineer, Mr. W. Nisbet Blair, and the Superintendent of the St. Pancras Destructor Works.

Deptford Cattle Market Refuse Test.—In this test 6 cwt. 2 qr. of slaughter-house offal were

[136] *Vide* paper on "The Disposal of Town and other Refuse by Burning," by James Deas (*Journal of Sanitary Institute*, vol. xvi., page 17.)

mixed with 12 cwt. of gasworks breeze, making a total of 18 cwt. 2 qr. The whole quantity was completely consumed in fifty minutes.

The residuals amounted to 2 cwt. 3 qr., or 14·86 per cent. The temperature in the combustion chamber is stated as having been over 2000 deg. Fah. This test tends to prove that this class of refuse can be successfully dealt with in a Beaman and Deas furnace in a proportion of 1 of refuse to about 1¼ of coke breeze.

Whitechapel District Board of Works Test.—This test was made by the Whitechapel Authorities in March, 1897, as some difficulty is experienced in the cremation of vegetable garbage by the destructors (Fryer's) at present in use in that district.

As a result of the test, Mr. J. Paget Waddington, the engineer and surveyor to the Whitechapel Board of Works, reported to the effect that the refuse, which consisted of about equal proportions of green vegetables and wet straw collected from the Spitalfields Market, together with rough house refuse from the Whitechapel district, was conveyed to Leyton and consumed in the Beaman and Deas furnaces at an average rate of 24 tons per cell per 24 hours. The quantity of clinker produced was 20 per cent. of the whole, and resulted mainly from the house refuse in the mixture. The clinker was of excellent quality, being hard and clean, and no unconsumed refuse was drawn from the furnaces while clinkering operations were performed. The temperature of the combustion chamber was maintained at a high degree during the time the refuse was being burned, and apparently at no period of the trial were unconsumed fumes given off from the furnaces.

Report and Tests by Sir Douglas Fox, M.I.C.E., on the Leyton Refuse and Sludge Destructor, erected under the Beaman and Deas patents:—As the installation at Leyton is, so far as I am aware, the first destructor which satisfactorily deals with the disposal of pressed sewage sludge, and as the works have excited considerable interest amongst public Authorities, the details of a test and examination conducted in April, 1897, by Sir Douglas Fox, cannot fail to be of interest to municipal engineers and surveyors. The particulars are as follows:—

"*Construction of Plant.*—The plant consists of eight destructor cells, built in pairs back to back. Each pair of cells has a common combustion chamber, from which the products of combustion pass into the main flues leading to two 96-horse power Babcock and Wilcox water-tube boilers, and thence by underground flues to a chimney 150ft. in height.

"The refuse to be consumed is charged through hoppers (which have no doors, but are usually covered with the refuse) on to an inclined hearth leading to a horizontal grate, the bars of which are set very close together. The ashpit is closed and a forced draught, at a pressure of about 2in., is supplied by a fan. On the side of the grate opposite that from which the refuse is fed in is a fire-brick chamber wall, and beyond this is a narrow vertical fire-brick chamber (called the combustion chamber), where the burning gases meet a secondary air supply, designed to aid the consumption of any unoxidised products which they may contain.

"The refuse about to be burned, lying on an inclined hearth, is partially dried by the radiant heat from the refuse which is already burning on the grate; and when it is drawn down on to the grate does not smother the fire, but begins to burn readily.

"*Outline of method of Trial adopted.*—A twelve hours' trial was carried out on Tuesday, March 30th (1897). Two pairs of cells were used, the remaining two pairs being left cold throughout the run. In the course of the trial the character of the refuse burned, and the quantity of refuse consumed, the amount of water evaporated in the boilers, and the weight of clinkers produced, were observed and determined. A special examination was also made of the nature of the escaping gases, and numerous samples for analysis were taken. The temperatures of the combustion chamber and of the flue gases were also ascertained, and the results in detail are set forth below.

Character of the Refuse Consumed.—The refuse consumed consisted of a mixture of ordinary *house refuse and filter press cakes of sewage sludge* from the Leyton Sewage Works. These were used as nearly as possible in the proportion of two parts of house refuse to one part of sewage sludge by weight.

"Observation of the character of the house refuse during the day showed that it was fairly dry (the weather being fine), but of rather poor quality from a heat-producing point of view; that is to say, the quantity of cinders was small, such refuse of household fuel as was present being to a great extent merely fine ash, containing but little combustible material. A considerable part of the refuse consisted of old tins and crockery, and there was also a good deal of green vegetable refuse, probably more than the usual average.

"The other material consumed—the sewage sludge—arrived from the filter presses in a wet, pasty condition. It was analysed both for moisture and the percentage of combustible material (carbonaceous matter) which it contained. The proportion of water exhibited some fluctuation, as is apparent from the following analyses:—

	Water per cent.
Sample A	61·23
Sample B	68·50
Average	64·86

"The average amount of combustible carbon was also determined. Carbon calculated on the dried sewage cake, 18·49 per cent. This quantity corresponds with 6·50 per cent. of combustible carbon on the wet sewage cake containing 64·86 per cent. water.

"It will have been seen from these figures that not only is the sewage cake very wet, but that it contains only a small percentage of combustible matter. A mixture of one part by weight of this material and two parts of house refuse of low quality is therefore a very poor fuel.

NOTICE.—On and after 31st March next the Annual Subscription to this Journal will be raised to 12s. 6d. to all NEW Subscribers. NO ADVANCE will be made to our friends whose names are entered on our Subcription list prior to that date, so long as they continue to Subscribe.

THE SANITATION OF DOMESTIC BUILDINGS.

By Frank Latham, C.E., M. San. Inst., &c., Assistant Surveyor, Borough of Margate.

CHAPTER VI.

Section 1. (*continued*).

Some of the most sanitary forms of water-closet apparatus now in use are constructed on the wash-down principle, which provides the foregoing desiderata in a very satisfactory manner. The up-to-date pedestal valve closet (Fig. 56) might

Fig. 56.

be placed one of the first on the list of sanitary closets, recent improvements having brought it to the front. This closet is made on the wash-down principle, but in order to retain a deeper seal of water in the trap, without giving rise to the soil and paper not clearing the basin, a valve is placed at the mouth of the trap, which opens upon the handle being raised for flushing, and upon so doing the water seal is at once lowered to the ordinary

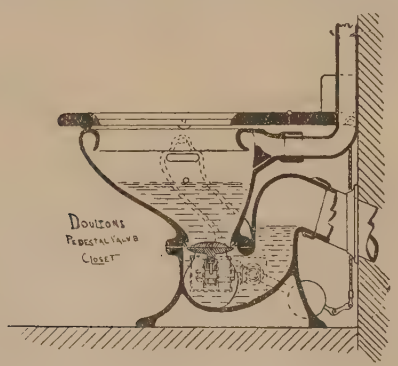

Fig. 56.

depth of the trap, and when the valve is replaced is again heightened by being held above its level. The best of these closets are simple in construction, nearly as much so as any apparatus, there being no open spaces such as existed in the old forms between the valves and water in trap, for the collection of foulness to be let loose into the house upon the valve being opened, nor is any extra ventilation required, owing to the valve being always below water level. The pedestal valve closet is especially adaptable for private houses and places where they are not subjected to rough usage, as the valve upon being damaged would not retain the extra amount of water required. There is also a likelihood, as in the plug closet, of paper getting between the valve and basin, thus letting the water escape; but even then the closet is not rendered unsanitary, provision being made, as before said, for the ordinary height of water in the trap to cover the valve, so that it is always under water.

In most valve closets an overflow pipe is fitted near the top of the basin to prevent its running over in the event of the valve in the flushing cistern getting out of order and causing flooding in the closet. This flooding is an occurrence not likely to take place often, but it requires guarding against, and in a proper manner. Many closets have been ridiculously rendered insanitary by the fixing of this pipe. It has been trapped and taken direct into the soil pipe, and, of course, there being little or no water to pass through it, it becomes unsealed, and remains so to ventilate the drains into the house until discovered and rectified. It has also frequently been connected in the valve chamber, a box between the trap and

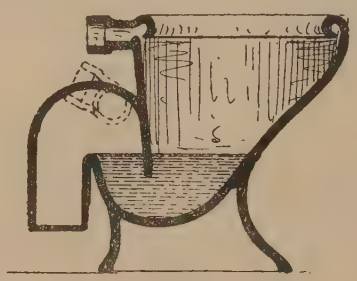

Fig. 58.

valve, existing in most valve closets, and which would convey the foulness of this chamber into the house. The pipe should be as short as possible, properly trapped, and connected with the outlet side of valve box, and the apparatus so constructed that the pipe and trap may be simultaneously flushed with the closet basin by means of the flushing rim, as is the case in Jennings' "Era" and Dent and Hellyer's "Optimus." This arrangement equally applies to the pedestal valve closet, which should always be provided with an efficient overflow.

All pedestal closets should be provided with lead safes underneath, each having an inch waste pipe taken through wall into external air, with its end covered with a brass flap valve to prevent draught. Equally efficient to the valve closet, but of different construction, is the syphon action apparatus (Fig. 57). This closet is constructed with the best form of wash-down basin, its chief features being that the trap in connection with the basin is carried up higher than usual. This affords the advantage of the water standing higher in the basin, giving a safer seal than usual, and less exposed surfaces to become soiled, the water surface being sometimes 12 by 10, and the depth of seal in trap 4in.; but with the assistance of the syphon action occasioned by a second trap on the outgo, which sets up a vacuum upon the apparatus being flushed,

the basin is enabled to properly clear itself of its contents. Several of these syphon closets (Jennings' Century) have been fitted in connection with the public lavatories at Margate, and also in the prisoners' cells in the Police Station, some having been subjected to unusually hard wear for four years, and up to the present are as good as new, and have given perfect satisfaction.

Next comes the ordinary wash-down closet (Fig. 58), which, when properly shaped, gives good

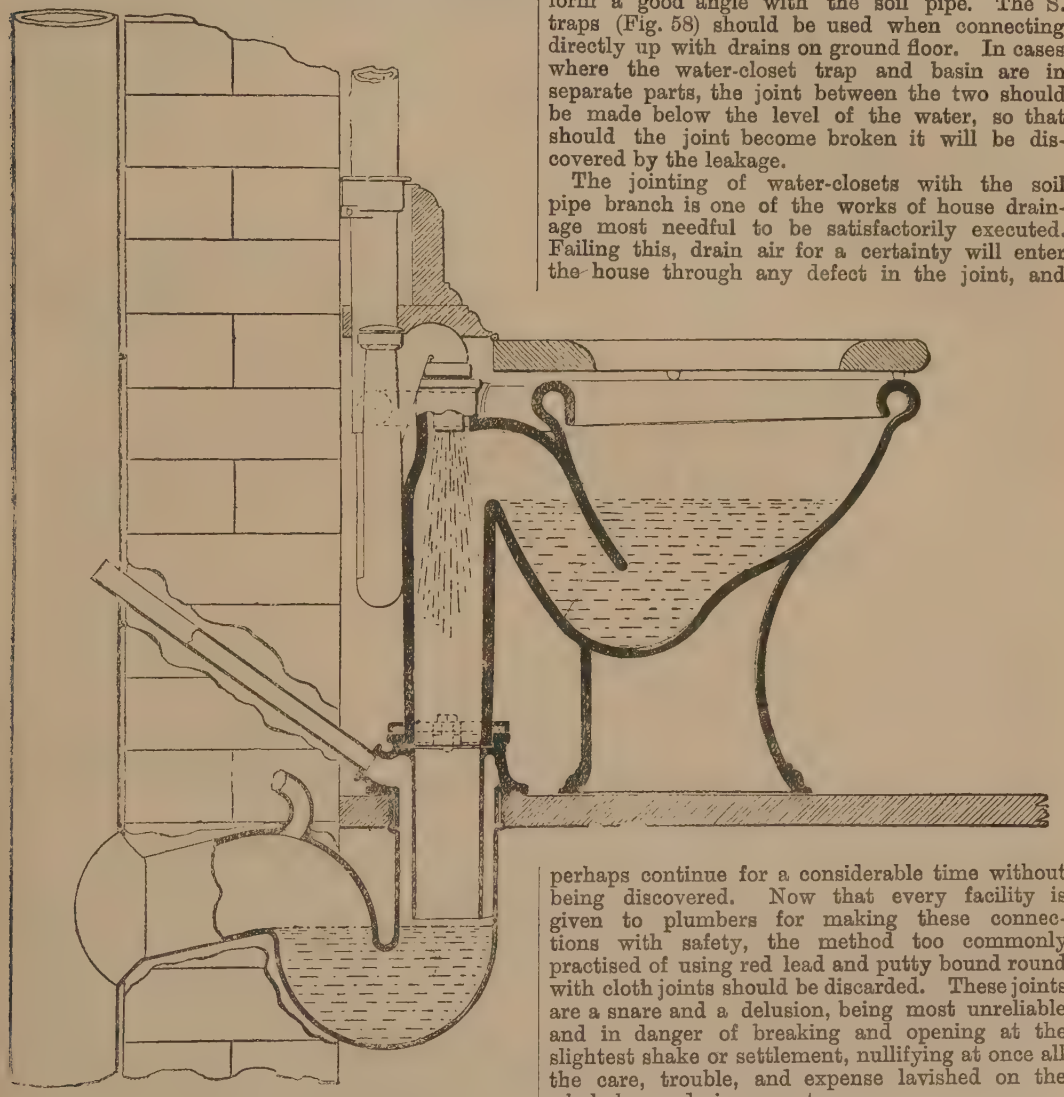

Fig. 57.

water surface, and with a sound flushing rim is an inexpensive and sanitary apparatus. This closet consists merely of a basin and trap, generally made in one piece, and so constructed that the soil is at once immersed in a good body of water, and upon being flushed is delivered directly into the soil pipe. A number of these forms of wash-down closets (Doulton's "Simplicitas") have been fixed under the author's supervision, and given great satisfaction.

All closets should be manufactured with proper flushing rims, which should cause the water to thoroughly wash clean the whole of the surface of the basin. The outlet pipes of closets should always be connected to the branch soil pipe above the floor, as in Fig. 58, so that the joint with the soil pipe branch may be properly seen and not hidden from view, as is the case in Fig. 54. It will be found best to use water-closets with half S. traps (Fig. 56), when the apparatus is to be jointed with a soil pipe branch through a wall, as by so doing the joint remains in sight, and the outgo will form a good angle with the soil pipe. The S. traps (Fig. 58) should be used when connecting directly up with drains on ground floor. In cases where the water-closet trap and basin are in separate parts, the joint between the two should be made below the level of the water, so that should the joint become broken it will be discovered by the leakage.

The jointing of water-closets with the soil pipe branch is one of the works of house drainage most needful to be satisfactorily executed. Failing this, drain air for a certainty will enter the house through any defect in the joint, and perhaps continue for a considerable time without being discovered. Now that every facility is given to plumbers for making these connections with safety, the method too commonly practised of using red lead and putty bound round with cloth joints should be discarded. These joints are a snare and a delusion, being most unreliable and in danger of breaking and opening at the slightest shake or settlement, nullifying at once all the care, trouble, and expense lavished on the whole house drainage system.

TO OUR READERS.

The Editor solicits the co-operation of readers in making THE SANITARY RECORD *more attractive by means of pen-and-ink sketches, photographs, and diagrams. There are many phases of sanitary work which lend themselves admirably to illustration. By this means not only individual articles, but the journal as a whole will be heightened.*

THE SUCCESS OF VACCINATION AND OTHER PREVENTIVE MEASURES IN SMALL-POX.

By MEREDITH YOUNG, M.D., Mast. Surg., D.P.H., Medical Officer of Health and Med. Supt. Crewe Corporation Hospitals.

(Continued from page 255.)

Nurses and Attendants.—In this special class I propose to consider briefly the cases of 20 persons, 12 of whom lived inside the small-pox hospital and 8 outside. All these persons, owing to their occupation, were exposed directly on innumerable occasions to infection from the most virulent, and, indeed, from all kinds of cases of small-pox. The nurses, for example, must have inoculated themselves time after time with variolous matter, and this surely affords a crucial test of their protection. The hospital attendants, cooks, ward-maids, laundry women, caretaker, porter, ambulance men, disinfector, &c., were in the wards many times during the day; and, of course, lived under the same roof, and in the next rooms often to the small-pox patients.

Those attendants who lived outside, such as extra ambulance men, extra laundry women, house disinfector, &c., by reason of their work, came into close and daily contact with infected clothing, infected persons, infected houses, &c. Yet of the 12 inside attendants, only 1, a nurse who had been twice vaccinated unsuccessfully, contracted small-pox, and the attack was a very mild, abortive, discrete one, so mild that she was never off duty during it. The others were all re-vaccinated, and escaped entirely.

Of the 8 outside attendants, 1 had had small-pox at the beginning of the epidemic, 6 had been re-vaccinated, and 1, who was employed only for a few hours in fixing a stove, &c., inside the hospital, had been vaccinated in infancy, and stoutly refused re-vaccination. The latter was the only person to take the disease. He was 53 years of age, had three small unfoveated scars, contracted a confluent attack, and was 50 days in hospital.

Remarks.—In connection with these statistics, I may say that the cases recorded affected, with only two exceptions of men from a common lodging-house, entirely the better class of artisans, and that the habits, work, surroundings at home and at work, were similar in both the vaccinated and unvaccinated class. No single one of the cases recorded came from an overcrowded or insanitary part of the town.

The previous health was always inquired into, but in only 2 fatal cases, 1 vaccinated and 1 unvaccinated, could any unsatisfactory history be discovered; these 2 cases were both alcoholic. I have several times been asked if in any case the copious eruption interfered with the appearance of the vaccination cicatrices, or rendered their discovery difficult; my answer has always been in the negative.

I have also been asked whether in any of the unvaccinated cases ill-health has been given as a reason for not having had the vaccination done; my answer has always been that I have been alive to the possibility of this, but have never found it to be the case.

Influence of Hospital on Surrounding Houses.—Taking the hospital as a centre, there are 17 inhabited houses with about 85 persons living in them within the quarter-mile radius. Only one case of small-pox occurred in these houses during the whole of the epidemic, and this was traceable to personal convection. This house was situated 250 yards from the hospital.

In the zone between the quarter and half-mile circles there are 1436 inhabited houses, with a population of about 7180 persons living in them. Of these 1436 houses 16 were visited by small-pox, all the 16 were outside the three-eighth-mile radius, and most of them were near to the extreme limit of the half-mile radius. In all 30 cases occurred in the zone between the quarter and half-mile radii.

I cannot think that these cases owed their origin to radiation of infection from the hospital, for the following reasons:—

(1) Three of the cases—affecting two houses—were imported from outside districts.

(2) The hospital was situated on a hillside, nearly at the top, at an elevation of 300ft. above sea level, whilst the average altitude of the affected houses was 190ft. above sea level.

(3) A fairly dense wood intervened between the hospital and the affected houses.

(4) Most of the affected houses were on the main road passing through Brighouse from the adjoining large towns of Halifax and Huddersfield, and this main road is literally infested with tramps. Others of the affected houses were on the side of the main road joining Halifax with Wakefield and Leeds, and this road is similarly favoured by vagrants.

(5) Had the hospital been the source of infection, one would have expected to find the greatest number of cases in the houses nearest to the hospital; whereas almost the exact opposite of this was the case.

(6) Had the hospital been the source of infection one would also have expected the greatest number of cases to have occurred at a time when the hospital contained the greatest number of cases, or the most severe cases.

But the greatest number of cases occurred in these houses towards the end of the epidemic, when the hospital contained only a few mild cases.

These considerations seem to me to render it highly improbable that this hospital acted as a centre of infection to the neighbourhood.

Measures adopted during the Epidemic.—Briefly, these were:—

(1) Free vaccination and re-vaccination by the hospital authorities of all persons who had been exposed to infection.

(2) Prompt isolation of all notified cases.

(3) Disinfection of houses, and whilst this was going on the inmates sent to hospital to have disinfectant bath, and have all clothing, &c., disinfected by steam.

(4) *Quarantine* of inmates of infected houses.

This calls for some special remark. It was only carried out throughout the whole epidemic by one of the districts concerned, the expenses being considered by the other districts as illegal and liable to be surcharged by the auditors of the Local Government Board. As a matter of fact, however, the

accounts for quarantine, which were heavy, met with no adverse remark from the auditors, the presumption being that in a time of epidemic, and more or less general panic, a Local Authority is justified in going a little beyond the actual limits of the law for the good of the town.

There was no difficulty experienced in getting people to remain in quarantine for fourteen days, even when shops and public-houses were concerned. The inmates were visited daily by a man who took a list of the provisions, &c., required, and obtained these at the Local Authority's expense, due regard always being paid to the reasonableness of the demands.

All quarantined houses were visited by me daily in order to detect any further case without delay.

Personally, I think that where prompt isolation of the patient, disinfection of the house, &c., and vaccination or re-vaccination of the inmates, can be carried out at an early date, quarantine is quite unnecessary; the house should simply be kept under medical supervision, and a certificate might be given in necessary cases to employers stating that all known precautions had been complied with, and that unless they heard to the contrary, no further danger need be feared from the house in question.

Where these precautions were not adopted by the inmates of infected houses, a note might be sent to the employers stating this and warning them of possible danger.

Of course the two objections to this system are, first, that to the popular mind it is "making fish of one and flesh of another," and it might not therefore meet with the approval of Local Authorities; and, secondly, that the whole matter would really be left to be decided by the employers, who might, on the one hand, refuse to continue the employment of persons who had adopted all these precautions, or, on the other hand, might continue the employment of those who had taken no precautions. But I have tried it in a fair number of cases, and met with no difficulty of this kind.

(5) As small-pox is frequently spread by mild cases, which are mistaken either for measles or chicken-pox, I advised my Board to include these diseases temporarily amongst those compulsorily notifiable, and to issue special notices that the "dual" notification by householders, as well as medical men would be insisted on. I feel confident that this would be of great benefit in checking the spread of an epidemic, and had it not been that it was towards the end of the epidemic when I suggested it, I think the Local Board would have adopted it. It appears to promise as much benefit as the temporary notification of diarrhœa in cholera times. I should state that when I made this proposal I was asked why it should not be extended to other diseases simulating small-pox, such as syphilis, acne, herpes, &c. I replied that syphilis and herpes, at least, were probably not of such common occurrence as to warrant this, and that none of them were so commonly confused with small-pox as measles and chicken-pox. These last two have, in common with small-pox, a sudden onset, and a febrile and infectious nature, which the others have not.

ERRATA.—The word "severe" in the first line of paragraph 3, page 255, should have read "mild."

INCORPORATED
Society of Medical Officers of Health.

RETURN CASES OF SCARLET FEVER.

A GENERAL meeting of the members of the Incorporated Society of Medical Officers of Health was held on Friday evening at the offices of the St. Giles' District Board of Works, High Holborn. The president, Dr. E. Seaton (Surrey), occupied the chair, and those present included Dr. J. Wright Mason, Drs. Gwynn, E. G. Yarrow, R. Dudfield, Lovett, Kempster, Woodford, E. A. Herrington, R. Shannon, E. M. Goodall, O. Field, S. Davies, E. H. Snell, W. Lake, St. Clare Shadwell, H. Kenwood, Bond, Wilson, F. H. Turner, J. H. Buchanan, E. Willoughby, E. Carnall, F. J. Allen (hon. sec.), and Mr. Wolff Defries.

Dr. J. WRIGHT MASON, M.B., C.M., D.P.H., M.R.C.S., Medical Officer of Health, Kingston-upon-Hull, and Hull and Goole Port Sanitary Authority, read an interesting paper on "Secondary Scarlatina and 'Return' Cases," which, he said, was based upon observations in hospitals of patients who had contracted a second attack whilst under treatment therein, secondary infection whilst under treatment at home, and of return cases occurring through patients discharged from hospitals disseminating the disease. Secondary scarlatina, occurring either in hospital or during home treatment, might be more severe than the primary attack, and might terminate fatally. The most susceptible period of life for secondary attacks are children between the ages of 5 and 8; they are more common among females than males, and more frequent and fatal in the autumnal quarter than in any other season of the year. From the clinical history of such cases the primary infection is usually mild and attended with little constitutional disturbance, and it would seem as if when those persons are again exposed to infection they may be susceptible to a second attack. Further observation showed that some families are more liable than others, whilst some enjoyed immunity. This natural power of resistance was found to present very remarkable degrees of variation in different persons and families. In secondary cases the whole virulence of the disease was most frequently concentrated in the throat, the joints swell, and the patient may be said to have a rheumatic attack. On the other hand, a secondary attack may be so mild that it may pass unrecognised, and may be a source of infection on the discharge of the case or the supposed convalescence of the patient at home. Secondary inspections were more common in urban than in rural populations, possibly owing to the overcrowding and congregation of the children; they most frequently occurred in small houses, the infection being accelerated by the attempted isolation of a case or cases. Secondary cases were less common in hospitals, and this was attributable to, he believed, increased air space, better ventilation, and grouping of cases according to the various stages of convalescence, which by diluting the infective material lessens the susceptibility to secondary infection. He did not agree with Gottstein's theory that certain acute specific diseases are definitely held to confer immunity, and that scarlatina, small-pox, and

measles are invariably held to do so. The history of scarlatina during the last fifteen years shows a gradual diminution in the average vitality, and the cases generally have been of a mild type, occasionally rendering it very difficult to differentiate between scarlet fever and non-specific ailments. The recurrence of each succeeding epidemic wave is influenced and characterised in its fatality by existing and varied meteorological conditions, and the tendency to spread is increased by atmospheric humidity, especially the absence of wind or rain. They must not, however, forget the important part that the introduction of hospitalism has played in minimising the vitality and reducing the infective material and its natural influences. Secondary scarlatina is more common than was generally recognised, and had, he believed, only been observed since the adoption of the notification of infectious diseases. Although he was not prepared to submit reliable statistics appertaining to secondary scarlatina, investigation in this direction was worthy of consideration. Return cases of scarlet fever, apparently resulting from the return home of the patient after isolation, were always a cause of anxiety to those responsible for the administration of infectious diseases hospitals, but he was not prepared to argue that this is an indictment against the administration of such institutions, as return cases occurred in the best administered hospitals. Return cases were altogether unavoidable, and their occurrence in a certain proportion was universal wherever hospital isolation is practised. Although a great number occurred after hospital isolation, their frequency was far greater than those treated at home. At Hull out of 2032 cases treated in hospital there were 81 return cases, or 3·9 per cent.; but out of 3487 cases treated at home there were 987 infections, or 28·3 per cent. It was generally acknowledged that the period when these return cases were most prevalent was in two seasons of the year, but more numerous in the autumnal quarter. This, he believed, was due to a very great extent to the overcrowding of the hospitals, with the consequent more or less premature discharge of patients in order to facilitate the admittance of others. But from a public health point of view, was this practice advisable? Notwithstanding the fact that there are risks of infection from the patient if he be too long delayed in an infected atmosphere, Local Authorities should make every provision for patients, and provide each hospital with convalescent sections. The probability of patients propagating the disease on their discharge would then be greatly reduced. Dr. May, after mature experience, states that he knows of no positive proof or indication as to when infection no longer exists in a scarlatina patient. The varied causes accountable for return cases Dr. Mason summarises as follows:—(1) Imperfect disinfection of clothing; (2) infected material being stored in the cavities of the mouth, nose, and lungs; (3) discharges from the ear and nose; (4) unrecognised secondary scarlatina patients whilst in hospital; (5) the specific poison which is stored up in the body for a considerable period, not being eliminated, disseminating the disease to healthy persons. Then they must not forget the liability of persons becoming infected in the ordinary manner. The average period of infection in the statistics he had given was about fourteen days, but he had frequently observed that when direct infection was conveyed by a patient, it occurred two or three days after their return home, and the remark equally applied to cases isolated at home. The more severe the attack the longer was the case likely to be infective. He agreed with Dr. Boobbyer that return cases occurring in a household are of greater severity than primary cases, and attended with higher mortality rate. In reference to the length of time isolation should be practised, Dr. Neech, after observing some fifteen thousand cases, stated a minimum period of fifty-six and a maximum period of ninety-one days' retention in hospital may be considered safe until the contrary was proved. It was generally accepted that scarlatina in its causation and dissemination was little influenced by sanitation, but there were some facts which pointed to a close relationship between the fatality and unhealthy dwellings of our crowded cities and towns. The conditions which tended to promote general unhealthfulness had a controlling influence over a general mortality, and in scarlatina sanitation would not only improve the general healthfulness of a community, but render them able to survive any illness, and be the less likely to propagate disease. A certain percentage of secondary scarlatina and return cases was unavoidable, but the number, especially those arising from home treatment, would be greatly reduced were the community to appreciate more fully the infinite advantages of infectious diseases hospitals. They were apt to forget that the seclusion of a patient removes a centre of infection. If diseases are preventable, why not prevent them? had been the remark of an eminent personage. Then there was a necessity of providing these hospitals with convalescent wards, which together with the grouping of all cases, according to the varying stages of the disease, and efficient disinfection of mouth, nasal, and aural cavities, and the patients' effects before discharge, and the issuing of precautions to the patient not to immediately associate with healthy persons, had minimised any possible source of infection and danger arising from secondary and return cases.

Dr. E. M. GOODALL, of the Metropolitan Asylums Board Hospitals, said this was a subject on which he naturally felt strongly, but imperfect disinfection by Local Authorities had something to do with return cases, some of which were also due to those sent out from the hospitals. But it was exceedingly difficult to say when a patient was free from infection. A patient might be sent out in such a condition that it was absolutely impossible to detect anything the matter with him, and yet he might give rise to other cases. He thought there was too much overcrowding at home rather than in the hospitals. Would they prevent return cases by having convalescent wards to the hospitals? His impression was it would not make a bit of difference. So far as any human being could detect, the patients went out free from infection, and it was worthy of notice that they did not get the same number of return cases in regard to diphtheria patients.

Dr. GWYNN, Dr. S. DAVIES, Mr. W. DEFRIES, Dr. WOODFORD, Dr. WILLOUGHBY, Dr. TURNER, Dr. R. DUDFIELD, Dr. ALLEN, Dr. THOMAS, and other speakers having contributed to the discussion,

Dr. MASON replied, and the proceedings closed with the usual compliments.

THE SANITARY INSTITUTE.

WATER-BORNE TYPHOID FEVER AND THE PURIFICATION OF WATER SUPPLIES.

A SESSIONAL meeting of the members of the Sanitary Institute was held at the Parkes Museum, Margaret-street, W., on Wednesday, 9th March. Dr. Shirley Murphy, M.R.C.S., Medical Officer of Health to the L.C.C., presided, and there was a good attendance of members.

Dr. CHRISTOPHER CHILDS, M.A., M.D. (Oxon.), D.P.H., lecturer on bacteriology in relation to hygiene at the University College, read a paper on "Water-borne Typhoid Fever." He said there were three aspects of the subject:—(1) Proofs that typhoid fever is frequently water-borne; (2) ways in which infectious material is conveyed from the patient into water used for drinking; (3) means by which this pollution may be prevented. Ample evidence with regard to the convection of typhoid fever by water was to be found in numerous reports to the Privy Council and to the Local Government Board, in the records of the late Ernest Hart, Dr. Budd, and many other observers. Having examined the nature of typhoid fever poison, Dr. Childs explained the way in which that fever may be conveyed from a patient to other individuals, which were three, viz.:—(1) By contact with the body, clothing, bedding, utensils, and other things which had been polluted with the discharges of the typhoid fever patient, unless care has been taken with regard to cleanliness and disinfection; (2) through the air, coming either from the soil or from drains, sewers, cesspits, or other deposits which had been contaminated with the discharges from typhoid fever patients; (3) through ordinary food, especially drinking water and milk, which had been exposed to air contaminated in the ways mentioned, or had been polluted by deposits, leaking cesspits, drains, sewers, &c., containing discharges of typhoid fever patients. It was probable also that the poison is not unfrequently

CONVEYED BY SHELLFISH

which had been in contact with polluted water, and possibly through ices, watercress, and various other food materials which had not been cooked before being eaten. Authorities differed as to which was the most frequent channel through which the poison is carried. The condition of the soil near and underneath houses might also be an important factor in the production of typhoid fever—a possible source which had not received much attention in this country. In tracing out the origin of attacks they were bound to take all possibilities into consideration, and it was further desirable to make allowance for some possible channel or manner of convection with which we are as yet unacquainted. If in dealing with the complicated problem they were to wait for absolute proofs of the origin and manner of convection, they would remain continuously inactive. Whatever their differences of opinion, if they used the knowledge at their disposal with regard to the causes of typhoid fever they would reduce the mortality from that disease to a minimum—from several thousands per annum to a few hundreds, or even less. If they could ensure notification and isolation, complete disinfection, protection from sewer gas and fæcal emanations, prevention of pollution of soil and water, with organic refuse and typhoid excreta, they would in England and Wales alone save some 4000 lives, obviate prolonged sickness and suffering to some 40,000 persons, and lighten the rates by some hundreds of thousands of pounds. The most important measures for the prevention of typhoid fever were thorough disinfection, correction of insanitary conditions in houses, drains, sewers, &c., protection of the soil and water from pollution, and the protection of our water supplies, was the one measure calling for immediate action. Up to the present time little or no effective attempt had been made to secure a thorough and systematic prevention of pollution of our water supplies throughout the whole kingdom. The Public Health Act, 1875, the Rivers Pollution Prevention Act, 1876, and the Public Health (Water) Act of 1878, were inadequate for securing general protection. We chiefly relied upon water companies and Sanitary Authorities for securing us against the introduction of

POISONOUS MATERIALS

into our drinking water, but under the existing state of the law the obligations of the companies and the powers of the Sanitary Authorities for thorough and constant supervision were so insufficient that we had little ground for confidence. We had adopted the pernicious habit of trusting almost entirely to chemical analysis, and more recently to bacteriological analysis, for detecting pollution, without investigating the surroundings of the source, the tributaries, and the course of the supply, nearly always without inspection and supervision necessary for the prevention of accidental, careless, or wilful pollution of the water. Analyses could only detect the pollution after it has taken place, and as a rule water-borne outbreaks of typhoid fever occur with explosive violence. Combined with thorough and regular inspection of the supply from its source to its distribution, chemical and bacteriological analyses were of great service, for they could indicate pollution which could not be detected by inspection, but if relied upon alone they give a false sense of security. Too often pollution was only discovered by an outbreak of typhoid, and then it was realised too late that expenditure for a proper supervision of the water would have been a safe and wise investment, would have prevented much sickness, loss of life, and loss of money. Dealing with the chief requirements for the prevention of pollution, Dr. Childs contended that the first requirement was thorough, regular, and systematic inspection of the supply from source to distribution, supplemented by bacteriological analyses and expert examination.

STRINGENT REGULATIONS

should be laid upon the water companies, and the Sanitary Authorities should have full powers of inspection of the water supply of their district, whether its sources were within or without the area of their jurisdiction. Wilful or careless pollution of any water supply should be treated as a penal offence. Authorities, representative of the chief interests concerned, should be appointed for each watershed area of the kingdom, with powers to take prompt measures to prevent any threatened pollution, or to abolish detected pollution, and should be responsible for the administration of the laws respecting the protection of water within their dis-

trict. Having referred to the defects of the existing law, he pointed out that one drawback was that the present powers of the Sanitary Authorities were enabling, not compulsory. Considering, too, that Sanitary Authorities were often themselves the greatest polluters, constantly subjected to local and vested interests, and to the incessant cry for the reduction of rates, it was not surprising their administration had not been attended with success. In fact, he could not conceive how, as at present constituted, the Local Authorities could be expected to maintain a constant and complete supervision and protection of our supplies. Nothing could be more obvious than that additional and more effective legislation is required, and the new Acts should be entrusted to an Authority who should be required to carry out its duties without delay, and who should act without fear or favour, unbiassed by local interests and jealousies. It was doubtful whether the County Councils could find time or would take sufficient interest in the enforcements of the Acts.

AN EXCELLENT MODEL

was found in the Lee Conservancy Board, which, whatever its defects, had worked continuously and systematically during thirty years for the purification of the Lee, and had worked with pre-eminent success. Major Flower, of whose work Dr. Childs spoke highly, advocated individual action as compared with action by committee, and he gave several instances relating to the towns of Luton and Hatfield to establish the point. It seemed almost superfluous to bring forward facts and arguments in order to prove the necessity for more effective legislation to prevent the pollution of water. To many it was a constant source of wonder and distress that the attempts at reform had failed again and again, and the cause, without doubt, lay chiefly in the ignorance and indifference of the people. One would have thought that a nation which prides itself upon its general common sense, cleanliness, and high sanitary instinct would have rebelled, and spared neither effort nor expense to prevent the yearly sacrifices of thousands, which is the result of this pollution. The indifference was not from want of warning, for leading sanitarians had never ceased to proclaim the causes of our typhoid epidemics, and the means of preventing them. Appeals to Parliament had been made in vain, and until the people were thoroughly roused from their indifference, until they were made conscious of the disgusting contamination to which our water supplies are so commonly liable, are

CONVINCED OF THE DANGER

to which they are exposed, that remedial legislation would be forthcoming. How could this indifference be overcome—indifference arising from ignorance of the simplest laws of nature and health? Only by persistent and systematic education, and therefore he suggested that the Council of the Institute—one of whose primary objects was to diffuse knowledge relating to sanitary science—should consider a scheme for diffusing knowledge relating to the causes of typhoid fever and the ways of preventing it. Much might be done by encouraging education with regard to the laws of health in schools, and by invoking the aid of the Press, pulpit, and platform. Might not the Conference on River Pollution form a permanent item at the annual congress of the Institute? He had dealt with the subject from a national point of view, the subject of the water supply of the metropolis being too large, complicated and exceptional to come within the scope of the discussion that evening. The demands he advocated on behalf of the protection of our water supplies might seem too large, too exorbitant, too adverse to vested interests, too exacting from the water companies; but he mentioned that if the companies were doing their duties little extra burdens would be laid upon them. As railway companies were responsible for the accidents to their passengers, so it was natural that

WATER COMPANIES SHOULD BE RESPONSIBLE

for the consequences of pollution occurring through culpable negligence on their part. However great these demands might appear, they would sink into insignificance when compared with the results which might confidently be expected from a wholesale abolition of water pollution. In conclusion, he proposed the following resolutions:—

"That the Council of the Institute be requested to consider the possibility of organising and carrying out a scheme for diffusing knowledge with regard to the causes of typhoid fever, and the means of preventing it throughout the whole kingdom."

"That the Council of the Institute be requested to consider the best means for obtaining new and effective legislation for the protection of our water supplies from pollution, whereby it shall be enacted that—

"(1) All Local Sanitary Authorities shall have free access to the water supplies—from source to distribution—which are distributed within their districts, whether the course and source of the water so supplied be within their district or not. That the Sanitary Authorities provide for the thorough and regular inspection of the water supplies distributed within their districts, and for the regular analysis of such water, as often as may be deemed sufficient, and that the results of such inspections and analyses shall be regularly recorded and published.

"(2) That the waterworks companies shall prepare and publish records of their water supplies, such records containing a full account of every source and tributary of the water supply, and a full account of all reservoirs, conduits, filter-beds, mains, and pipes by which the water they supply is collected, stored, or conveyed to the houses supplied; such records also being fully illustrated by maps, plans, and sections, showing the relation of all houses, drains, sewers, cesspits, and all deposits of organic refuse in the immediate neighbourhood of any part of the water supplied by them, and that all such maps, records, plans, sections, &c., shall be freely accessible for the purposes of inspection to the Sanitary Authority within whose district the water is supplied, and to every customer of the waterworks company.

"(3) That the waterworks companies shall be required to make regular, constant, and thorough inspection of all parts of the water supplied by them—from source to distribution—with a view to preventing wilful, careless, or accidental pollution; also to make regular analyses of the water supplied by them, so often as may be considered necessary, and to make and publish reports of all such inspections and analyses.

"(4) That the waterworks companies shall be made responsible for the consequences of the pollution of the water supplied by them, if such pollution could reasonably have been prevented.

"(5) Wilful or careless pollution of any water supply shall be regarded and treated as a penal offence.

"(6) That Authorities, representative of the interests concerned, be appointed for each watershed of the kingdom, who shall have the general care and supervision of the waters within each respective watershed ; shall take prompt measures to prevent any threatened pollution, and to arrest any detected pollution of any water ; and shall be responsible for the due and effective administration of the laws respecting the protection of water within their districts. (Applause.)

Mr. E. WHITE WALLIS read a letter from Dr. Sims Woodhead, who expressed concurrence with Dr. Childs, that typhoid fever is frequently waterborne, but pointed out that in water the typhoid bacillus was at a distinct disadvantage. It was only when there was a constant and recurring infection that there is anything like epidemic form. Experiments showed that the bacillus lived for much longer periods in the soil than in water. For this reason it was necessary that although the utmost care should be exercised in regard to the examination of every water supply, still greater care should be exercised in making examinations on the collecting grounds, and also of the ground in which the pipes and mains are laid. At present there appeared to be a kind of natural antagonism between Sanitary Authorities and water companies, which might be readily understood when it was remembered that the bias of the two sets of men was diametrically opposed. But it was right that the Sanitary Authority should be able to impose certain restrictions on the companies, though it was to be remembered that very often Sanitary Authorities themselves were often great sinners in the matter of the pollution of water supplies. It was hardly to be expected under present conditions that just bye-laws would be held by Local Authorities unless they were made responsible for collecting areas, or some Central Authority had power to come to them with advice and control whenever matters of dispute arose. He could not help feeling that Major Flower was right when he suggested that compulsory powers should be obtained to deal with many of these matters. It was to be remembered that many water companies had to work under very great disadvantages, being frequently in the position of having to make bricks without straw, while in many instances they had to rely on outside and unofficial advice for their knowledge of the advances of bacteriology and chemistry. What struck him was that the time had now come for the formation of some central board of advisers, and of appeal to which water companies, whether public or private, or a Sanitary Authority, might apply in matters concerning improvements and alterations, and to whom also consumers might appeal in cases where they are not satisfied with the present condition of any water supply. If to such a board compulsory powers could in any way be given, there was little doubt that a considerable step would be made towards the solution of an exceedingly difficult and important problem.

Major LAMOROCK FLOWER, engineer to the Lee Conservancy Board, thanked Dr. Childs for his references to himself, and contended that after many years' experience, the way to get rid of pollution was by individual, rather than committee action. Twenty-seven years ago he had been given a free hand, which he still retained, but where interference had taken place with himself in his duties there, failure had to be recorded.

Dr. LOUIS PARKES seconded the resolutions proposed by Dr. Childs, and said that after the publication of the Local Government Board report on the Maidstone epidemic, the Council of the Institute might see its way to getting a strong deputation to the Local Government Board with regard to the necessity for taking action in regard to safeguarding the public water supplies of this country. With regard to Dr. Woodhead's letter, it always appeared to him that though the typhoid bacillus might not live long in reservoirs or rivers, it was possible that this might not be the case in dark mains and cisterns. Perhaps there might be some evidence taken on this point at the Maidstone inquiry.

Professor J. LANE NOTTER, Dr. RIDEAL, Dr. NEWSHOLME, Mr. J. A. WANKLIN, Dr. R. DUDFIELD, Mr. WOLFF DEFRIES having spoken,

The CHAIRMAN said he was afraid the great difficulty underlying the whole question was that human nature is not always to be relied upon. One had to design one's machinery in such a way that the frailty of human nature can be the least capable of inflicting injury. It seemed to him that there was one broad principle that ought to underlie the water supply to communities, *e.g.*, that it should not be supplied for profit. The moment they introduced a supply for profit, whether it were by company or Sanitary Authority—he was afraid that some Sanitary Authorities must be definitely accused of trading in water—the community was exposed to risk. Water was a necessity, and it ought to be supplied in a fit condition for its purpose, and it ought to be supplied without profit at the lowest price that the community can pay for it. The moment it became a trading concern difficulties arose, and that was the point they ought to bear in mind, and which he should be very glad to think that the attention of the Legislature would be directed to, for he believed that Sanitary Authorities were indulging in the habit of trading in water, and were guilty of a course of action prejudicial to the interests of the community.

The resolution was then agreed to *nem. con.*, and a hearty vote of thanks was passed to Dr. CHILDS, who briefly replied to some of the points raised in the discussion.

On the proposition of Professor NOTTER the usual compliment was accorded to the Chairman, and the proceedings closed.

LOCAL AUTHORITIES AND SLAUGHTER-HOUSES

THE Scotch Local Government Board has just issued a circular to Local Authorities of landward districts directing their attention to the provisions of the new Public Health Act with regard to slaughter-houses, and recommending every Local Authority within whose district a slaughter-house exists or is proposed to frame bye-laws under the Act, supplying also a form of bye-laws for adoption. The matters which may be regulated by these bye-

laws are :—The conduct of the business, and the structure of the premises in which it is carried on —the object in both cases being to prevent or diminish the noxious or injurious effect of the business. The bye-laws may also regulate the mode in which the application for the sanction of the Local Authority to the establishment of the business is to be made. No power is given to make bye-laws as to the situation of slaughter-houses. The intention of the Act obviously is that the Local Authority should satisfy themselves regarding the suitability of the site before giving their sanction to the establishment of the business or granting a licence for the premises.

The following requirements ought to be insisted on :—Neither the slaughter-house nor the lairs for cattle in connection therewith should be within 100ft. of any dwelling-house, and the site should be such as to admit of free ventilation. The slaughter-house should not in any part be below the level of the adjoining ground, and there should be provision for effectual drainage. An adequate water supply should be provided, and should be so arranged that the walls, up to a height of 6ft., may be washed by means of a hose. There should be no habitable room or loft over the slaughter-house or lairs. Although the Act authorises the making of bye-laws for the structure of the premises, the Board think that Local Authorities will find it advisable to deal with the structure in the manner suggested for dealing with the site. The Local Authority should either see that the structure is suitable before they give their sanction, or should only give their sanction on the applicant coming under an obligation to make the structure suitable within a specified time. The Local Authority of any landward district, either singly or in combination with other Local Authorities, is authorised to provide a public slaughter-house, and to borrow for that purpose on the security of the Public Health general assessment and of the rates or dues leviable by them for the use of the slaughter-house.

The provisions as to sanction and annual licence, and as to advertising the intention to apply for the same, appear to be applicable in the case of a public slaughter-house as in other cases, and there will be a like appeal to the County Council and to the Board as in other cases. If the Local Authority are careful in giving sanction only where the situation, construction, and sanitary arrangements of the premises are satisfactory, and if they frame and enforce suitable bye-laws, and carry out efficient inspection, it is not probable that nuisance will arise in any slaughter-house within their district. But if nuisance should arise, the fact that the business has been established with the sanction of the Local Authority, and that the premises are duly licensed in terms of the Act, will not prevent the Local Authority taking proceedings to have the nuisance removed.

WATER ANALYSIS AT MAIDSTONE. — The Somerset House report in the disputed analysis case was received on Tuesday last, and was to the effect that "there were grounds for believing the water was not liable to contamination, and that its use for potable purposes was not likely to prove injurious to health." The Bench refused to make an order to close the well, and dismissed the case.

Sanitary Inspectors' Associations.

SOUTH WALES AND MONMOUTHSHIRE.

A SPECIAL meeting of the Association was held in the Town Hall, Cardiff, on Saturday afternoon, March 5th. In the absence of the President (Dr. Williams, Medical Officer for the County of Glamorgan), who is indisposed, Dr. Walford, Cardiff, Vice-president, presided. There were also present Dr. Herbert Sims (Hon. Treasurer), Mr. W. Fraser (Chairman of the Council), Messrs. W. Lloyd Marks and D. Vaughan (Vice-chairmen of the Council), together with a large attendance of members, including Messrs. E. A. Leyston, Spencer E. Jones, Llewellyn Davies, David Jenkins, James Jones, W. John Hughes (members of the Council), &c., the Honorary Secretary, Mr. J. Towy Thomas.

The following gentlemen were elected hon. members of the Association :—Dr. T. J. Dyke, M.O.H., Merthyr; Dr. Evan Evans, M.O.H., Llanelly, Carmarthen; Dr. G. H. Brown, M.O.H., Brynmawr; Dr. E. Garrod Thomas, Llytha Park, Newport; Dr. W. E. James, M.O.H., Abercarn; Dr. Trafford Mitchell, M.O.H., Gorseinon; Mr. W. J. Jones, Surveyor, Rhondda Urban District Council; Mr. D. W. Jones, Solicitor, Chairman Health Committee, Merthyr; Alderman Thomas Jones, Chairman Sanitary Committee, Newport.

Mr. M. Roderick, Road and Sewer Inspector, Rhondda Urban District Council, was elected an associate; and Mr. John Powell, Surveyor, and Chief Sanitary Inspector, Pontypool, a member.

Messrs. Llewellyn Davies (Swansea), and T. W. Warren (Cardiff), were elected scrutineers; and Messrs. E. A. Leyston (Barry), and D. J. John (Pontypridd), auditors, for the ensuing year.

The important work of the meeting was to discuss the best means of promoting "The Sanitary Inspectors' Superannuation Bill," &c.

The following resolution was passed, "That this meeting of Sanitary Inspectors unanimously presses its claims upon members of Parliament to support "The Sanitary Inspectors Appointment and Superannuation Bill, 1898," to be brought into Parliament during this session, as the only means inducive to render effectual assistance to carry out sanitary administration which the Legislature had in view in passing the "Public Health Acts."

Deputations were appointed to interview all Members of Parliament within the area of the Association, with the view of getting them to support the measure. The President, Treasurer, and Secretary were appointed to proceed to London on the day when the Bill would be introduced into Parliament, and interview the various members referred to, so as to secure their votes in favour of the Bill.

NORTH-WESTERN AND MIDLAND.

THE thirteenth meeting of the session was held on Saturday last at Liverpool. An interesting paper on "Public Health Problems" was read by Mr. Ernest Worrall. Owing to the great pressure on our space, we are compelled to postpone the report until next week.

NATIONAL REGISTRATION OF PLUMBERS.

MEETING AT BRADFORD.

THE annual public meeting of the Bradford District Council, in connection with the National Registration of Plumbers, was held on the 9th inst., at the Technical College, Bradford. Mr. Charles France (architect), presided, and was supported by Ald. Richard Hind (Master of the Plumbers' Company), Dr. Evans (Medical Officer of Health), Mr. James Watson (City Waterworks Engineer), Mr. J. H. Cox (City Surveyor), and Mr. F. W. Richardson (City Analyst).

Dr. EVANS, in seconding the adoption of the report, said that the work of registration was certainly progressing. He hardly needed to point out the value which all sanitarians attached to the efficiency of plumbers' work. It was very often the scamping of plumbers' work, or the employment of unqualified people, which was the cause of the preventible diseases which were the scourge of communities. He hoped the Bill for the Registration of Plumbers would have better fortune than it had previously had.

Alderman HIND said he was very glad to see the names of two Medical Officers on the list of public representatives of the Council, for much of the sanitary progress of any community depended upon the interest of these gentlemen. He acquiesced in Dr. Evans' expression of the hope that the Plumbers' Registration Bill would meet with a better fate this year than it had hitherto experienced. It was admitted on all hands that much of the preventable disease of the country was caused by bad plumbing work inside the house, and it was therefore regarded as most important that some provision should be made whereby any person who wanted to employ a plumber should be able to know whether or not the person whom he had in view had had the necessary and proper training. Speaking of the Plumbers' Company, he said that though for a time it had passed out of the hands of the plumbers, it was now interesting itself in the trade in a very practical way.

Mr. JAMES WATSON proposed a resolution "That this meeting reaffirms the desirability of the speedy passing into law of the Plumbers' Registration Bill." He said he had had something to do with the initial stages of the registration of plumbers in Scotland, for he was convinced that the plumbers very largely had control of the public weal, especially in congested communities. He contended that it was the bounden duty of Parliament, whose first object should be to see to the public health, to give the qualified plumber a status and standing by registration in order to encourage him to do his best for the community in which he lived.

Mr. F. W. RICHARDSON, City Analyst, then delivered a lecture on "Microbes and Sanitation," in which he described and illustrated the nature of microbes, the poisons formed by disease germs, the causes of the various preventable diseases, the conditions favourable to diseases and epidemics, the influence of filth, bad water supplies, and defective plumbing, and the importance of sanitation generally in regard to disease.

Votes of thanks to the chairman, the lecturer, and Alderman Hind closed the meeting.

Institute of Sanitary Engineers

THE SANITARY ADMINISTRATION OF BELFAST.

(*Continued from page* 261.)

(12) With regard to these water-closet regulations it may be pointed out that the Belfast Water Commissioners, a separate elective Trust, have, in addition to their water-waste regulations, a set of sanitary bye-laws upon these points, if anything, more stringent than those of the City Council. I am not aware that the double supervision arising from this has led to friction, or to a more careful inspection falling to the ground, as it were, between two stools.

(13) In the case of privies, which are, however, as far as possible discouraged, they, nor the ashpits under them, must not be nearer than 4ft. to any house, and—

(14) Not to be nearer than 5ft. to any domestic water supply.

(15) No ashpit, &c., to be allowed which would necessitate removing its contents through a dwelling-house.

(16) All privy-pits must allow of dry ashes being mixed with the other contents.

(17) And all ashpits must be covered from the rain, ventilated, and have impervious bottoms above the level of the yard. Pits for ashes only may approach no less than 2ft. from a dwelling-house, and 3ft. from a domestic water supply.

(18) As all are now cleaned out by the public scavengers at the public expense, they must communicate either directly or through an open yard, with a back lane.

(19) For many years no street has been permitted of less than 30ft. in width, and every street not passed before, I think, 1886, must have a back lane at least 9ft. wide (before that time back lanes were permitted 4½ft. in width).

(20) Every yard must contain, free of all covered buildings, a clear superficial area of 100 square feet, and otherwise of suitable dimensions. This, with the 9ft. back lanes, ensures a very good circulation of air round all houses, especially as by far the great bulk of working-class dwellings consist of two-storey four-roomed houses.

There is an interpretation, which I do not think can be borne out by the Act, that all yards to dwelling-houses must be upon the ground level, a regulation in general highly proper and convenient. There are, however, a limited number of cases, in connection with business premises, and mainly in the central parts of the city, where a strict adhesion to this rule, which is nevertheless enforced, does not seem to be desirable. There are many premises in the city, originally built for and well adapted in every other respect, as dwellings, and even of a comparatively high class, in which, through the extension of business, it has been found necessary to encroach upon the original yard space. Were it not for the adhesion to "red tape," a commodious yard of iron and concrete could be formed at what is really the dwelling-house level, and the salubrity of the premises be enhanced rather than suffer thereby. In justice to town officials, both in Belfast and, from my knowledge of other places, I cannot wonder they should cling as closely as

possible to stereotyped regulations. They are always the servants of a Corporation, elected at frequent intervals upon a popular franchise, and after giving citizens and their representatives alike full credit for honesty and public spirit, there yet remains room for the display of a large amount of "human nature," and a public officer is daily subjected to pressure from more or less influential quarters to render some regulation or other just a little more elastic in the applicant's most particular case.

No wonder they think that safety lies often in a rigid *non possumus*. Nevertheless, this need not prevent a judicious revision sometimes of rules, admittedly made in the first instance for the public benefit. The yards case, I think, may be one of these.

I may here remark that in Belfast the City Surveyor's department hold in practice that their duties of supervision cease as soon as the work has been completed, and that after it has passed their inspection further control should rest with the Public Health or some other department. This is only natural, though of course they hold themselves at liberty, at whatever time a breach of their regulations may be discovered, to take action with regard to it. In point of fact, persons building in the city have to give in all cases a written adhesion to a long list of printed sanitary regulations, drafted in the spirit of the foregoing, and also in many instances plans are not allowed to be passed until special undertakings have been given upon various sanitary and other matters.

Whilst the primary object of the Surveyor's department is to deal with new buildings, and its inspection is confined in the main to the task of seeing these properly carried out, the Public Health Department has its chief work in dealing with the existing condition of things, so far as the health of the community is affected by them. The work of inspection necessarily, therefore, occupies a position of much greater relative pre-eminence than in the Surveyor's department.

I may perhaps, in commencement, summarise the more important items of the bye-laws which the department has to give effect to, but in doing this it will be hardly necessary to mention all the Acts of Parliament which it administers, most of them being public Acts more or less familiar to you all. The first I deal with is

Lodging Houses.—These are (1) to be swept daily and washed out weekly; (2) notice to be given in case of infectious disease, and for disinfection; (3) proper water supply and accommodation for washing is to be provided; (4) there are rules as to absence of hangings and style of beds; (5) also rules as to separation of sexes.

Seamen's Lodgings.—There are separate bye-laws for these, in the main similar to the foregoing, but rather more strict. There also seems to be a power of inspection, and for making orders under the Medical Officer of Health, not mentioned in the former bye-laws. Taking into consideration the character of most common lodging-houses, I am rather of the opinion that, instead of weekly, they should be washed out twice a week at least, and should be lime-whitened twice a year.

Cowsheds and Dairies, &c.—Under the powers of the Contagious Diseases (Animals) Acts, 1878 and 1886, and the "Dairies, Cowsheds, and Milkshops Act, 1886," a set of bye-laws has been framed. (1) Cattle sheds must be "well lighted, drained, and ventilated;" (2) there must be a proper supply of water; (3) floor to be properly paved to avoid saturation; (4) space for each cow, 6ft. by 3ft., in addition to passage, &c.; (5) or equal at least to 400 cubic feet for each; (6) no entrance through dwelling-house, or passage for manure or animals through the same; (7) the yard to be properly paved; (8) proper dung pit, and the manure not to lie more than two days at a time, and provision for disinfection in case of disease; (9) all places to be swept and cleaned *twice* a day, and lime-washed twice a year. This latter provision is not enough. The Tramway Company whitewash their stables monthly, and the health of milch cows is of more importance surely to the community than that of tram horses! yet philanthropists are always crying out about the latter because they are in evidence, whilst dairy cows are for the most part out of sight; (10) no pigs to be allowed, or at the least they must be 20ft. distant; (11) all dairies and milkshops to be cleaned daily, and the vessels twice a day; (12) no cooking, meals, sleeping, or food taken in places devoted to the sale or storage of milk; (13) there are rules as to disease and closing if necessary; (14) also as to exclusion of persons having disease from contact with animals, or from such places.

Piggeries are under a separate set of bye-laws:—(1) Neither pigs or their manure are allowed to be within 15ft. of a dwelling house; (2) must be properly drained, and the floors asphalted or concreted, so as to prevent any soakage into the soil, and to allow of their being properly washed out; (3) there must be a proper manure pit (not sunk), and properly drained to a tank which must not be in connection with the public sewers; (4) the manure must be removed at least once a week, but *not* through a house; (5) must be lime-washed six times a year.

The consideration of these rules regarding animals suggests several questions for answer. One that obviously arises first is as to the propriety of allowing cows to be kept at all within the city bounds. The condition of a milk-giving cow perpetually shut up within walls does not seem a natural or healthy one, yet as this climate, with its absence of pasture in winter, and the general inclemency of that season, almost necessitates all cattle being under cover for nearly half the year, there is some difficulty in enforcing a change. Moreover, in the present condition of dairy farms in the country the exchange would, more often than not, hardly be an advantage from a sanitary point of view, and whether under Boards of Guardians as at present or under some future County or District Council, however intelligent, circumstances for some time to come would scarcely permit of inspection in the country being as strict as it is possible for it to be in a town. Whether in our own case that inspection is as strict as it ought to be is at least debateable. The enforcement of the rule, for instance, as to cleaning twice daily, just as in the washing of milk shops and their vessels, and of lodging-house floors, would require a whole army of Inspectors to see carried out with absolute certainty. Officers must obviously be content with such apparent compliance as may be suggested by the state of the place upon inspection. There might, however, be a greater strictness as to the condition of the floors. I have seen patches filled up with pebble stones in an uneven

and sunken condition, in which undesirable liquids could lie, and no doubt permeate the subsoil. Why also should not the same rule apply to piggeries, and nothing be allowed but asphalt or concrete? Again, why is the more important cow-house to be whitewashed only twice a year as against six times for the pig-sty?

Those who note the signs of the times will be ready to believe that we may be upon the eve of great changes as regards our milk supply. In this respect Denmark and some other countries are very much in advance of our own. Membership of an Institute such as this presupposes at least an elementary knowledge of bacteriology, and of dissemination of disease by means of the all-pervading microbe. Not alone typhoid and diphtheria, the infection from which can be guarded against by comparatively simple precautions, but tuberculosis is very readily conveyed through milk, and the latter is now recognised as especially the disease which pertains to houses. It is admitted that a very considerable percentage of dairy cows are affected with tuberculosis, and that much of that disease in the human subject has probably been conveyed by this means, and it is especially likely to be so where it has attacked the intestinal organs, as it so frequently does in young children; yet, except in the most general way, the law, either national or local, does not recognise, and takes no special precautions against this. It is now known that milk is also affected by micro-organisms in many other ways, in which its use, although not so far as is yet known, communicating any specific disease, must render it more or less injurious as an article of diet. It seems therefore quite clear that the keeping of cows and the distribution of milk require to be placed under much more stringent regulations than has yet been the case. For instance, the space occupied by dairy cows, whether in or out of town, should be very largely increased, as four hundred cubic feet seems a very inadequate allowance for so bulky an animal as the cow.

Then again, attached to every byre, where the cows are not actually at grass, should be a large yard, fully open to the air, but in part, at least, covered, into which it should be compulsory for them all to be turned for the greater part of the day, and subject to the same rules for cleanliness as the house itself. I would hope in time to go a step further, and to see at least the udders and the adjacent parts of the cow washed before each milking, and the cows groomed like horses at least three times a week, if not daily. Finally, that all milk supplied to the public should be first sterilised, and be delivered in closed cans or other suitable vessels. It may be urged, and with some show of reason, that the compulsory adoption of these measures would so enhance the cost of milk as to render its use all but prohibitory to the very poor. That it would somewhat increase the cost is pretty certain, but I doubt whether to so great an extent as might at first be imagined. It is astonishing how we find that new methods and appliances, which, when first introduced, were costly in the extreme, become, when once they are universally adopted, and therefore applied upon a large scale, as cheap as they formerly were dear. The community at large would, in the long run, probably be the saver by the diminution of the loss occasioned by death and disease. The working classes, too, who have benefited in an infinitely greater proportion than the classes above them by the cheapening during recent years of the national food supply, may well be asked to pay a little more to ensure safety in the use of one single article, the risk attaching to the use of which is neither trifling nor imaginary.

It is the members of the working class, however, with their control of votes, who will ultimately have to decide these questions for themselves. Our place for the present is so to formulate, and then form, such a healthy public opinion as shall permeate in every direction through all classes of society, so that, when the time comes, the majority shall be willing to decide these sanitary matters in a far-seeing manner for their true interest.

In regard to the bye-laws as to keeping of pigs, by far the easiest way for the Authorities would be to prohibit their being kept inside the town at all, because every poor person who has a yard a little larger than ordinary wants to keep one or two therein, and the proper supervision of all these must be one of the most troublesome parts of an Inspector's work. Nevertheless, to forbid them altogether would raise a terrific outcry, and the regulation merely has often been the source of friction. There is besides a very large amount of refuse food that would otherwise go to waste, or else be disposed of through some other channel, not perhaps altogether an undesirable change, because to judge from the character of much of the refuse one sees gathered up for this purpose it must often be unfit for use. Nevertheless, as all pigs' food is in Ireland cooked before using, perhaps the risk may be less than at first sight would be suspected, as a thorough boiling is an excellent germicide. Of course, too, the removal at very short intervals of so much household refuse prevents the accumulation in the ashpits of a quantity of stuff that would otherwise be liable to putrefaction, and is to that extent an advantage.

Perhaps the easiest way of checking the keeping of pigs in back yards would be to somewhat enlarge the area in which they may be kept—say, to 20ft., at least, from any dwelling-house.

(*To be continued.*)

NEW LAVATORY APPLIANCE. — Mr. J. N. Maskelyne, of the Egyptian Hall, has just invented another little contrivance for use with his registering locks, or for other purposes. It consists of an indicating door latch principally for use in lavatories. One of the objections hitherto in this class of article is that the whole of the word "Engaged" does not always show. In Maskelyne's indicator this is overcome by an ingenious device, the door not being properly fastened until the whole of the word "Engaged" appears in the opening. Another advantage is that the door can be opened from the outside with a key, in cases of emergency, and the indicator can be set to "Engaged" by the attendant, should the visitor neglect to do. The manufacture of the article is in the hands of Messrs. Thorpe and Salter, engineers and contractors, Red Lion-street, Clerkenwell, who are also the makers of Maskelyne's automatic and registering locks, which we see at all the principal lavatories in London and provinces.

General News.

SITTINGBOURNE.—It appears that steps will have to be taken shortly to procure a more adequate water supply.

LOUGHBOROUGH.—Additional water mains, at a cost of £1400, and other improvements in the water supply are contemplated.

SEVENOAKS.—The Sanitary Committee of the Urban District Council is considering the question of providing a public slaughter-house.

WEST HAM.—The Guardians have resolved not to institute any more prosecutions of parents for refusing to have their children vaccinated.

SUTTON-IN-ASHFIELD.—The District Council has decided to ask the Medical Officer, Dr. Nesbitt, to prepare a report on the cases of typhoid fever at Forest-side and New Cross.

LUDDENDEN, WARLEY, AND MIDGLEY.—The Urban District Councils of Luddendenfoot, Warley, and Midgley have requested the Halifax Corporation to supply their districts with water.

ECCLES.—The Town Council has resolved to apply to the Local Government Board for £1500 for the erection of a boiler-house and laundry, and for improvement at the Public Baths, Patricroft.

ROCHFORD.—The local scheme for providing a much-needed supply of water has been abandoned by the Council, as the quality of the water does not commend it to the approval of the Local Government Board.

WITHINGTON.—An important Local Government Board inquiry was opened on Thursday, the 10th inst., into an application made by the Urban District Council for sanction to borrow £5500 for the purchase of Baguley Lodge Estate as a site for an infectious diseases hospital.

LITTLEHAMPTON.—The Urban District Council met in committee on Thursday, the 10th inst., at the town offices for the purpose of considering a special report as to the proposed new water supply. The present supply during the summer months barely suffices for the needs of this promising town.

ILFORD.—At a recent meeting of the Urban District Council a letter was read from Mr. J. McCowan, Lord Salisbury's agent, stating that his Lordship was prepared to sell two acres of land at Ilford, at £600 an acre, as a site for houses for the working-classes. The letter was referred to the committee who had the matter in hand.

RETFORD.—The Local Government Board, with reference to the Mattersey water supply, has recommended that a scheme should be adopted which would include the parish of Mattersey Thorpe, and it has been resolved by the Rural District Council that Mr. Fenwick, the engineer, be instructed to prepare a plan for such a joint scheme.

CHELTENHAM.—The Town Council have decided to purchase the Baths for the sum of £2600, subject to the sanction of the Local Government Board for the necessary loan for the purchase-money, and for such alterations as may be decided on being obtained, and the Borough Surveyor has been instructed to report as to the best mode of converting and altering the Baths.

WITTON GILBERT.—A Local Government Board inquiry has been held *re* the borrowing of £900 for water supply.

YORK.—The Corporation has applied to the Local Government Board for sanction to borrow £2500 for hospital purposes.

LUTON.—The borough surveyor is preparing plans, estimates, &c., for an isolation hospital to be erected at a site near Spittlesea Cottage.

MANSFIELD WOODHOUSE.—The Urban District Council has applied for the Local Government Board's sanction to a loan of £3000 for carrying out the waterworks scheme.

TOTTENHAM.—The Urban District Council has received a communication from the Local Government Board forwarding sanction to the Council borrowing £1500 for the extension of the water mains in the district.

MELTON MOWBRAY.—At a recent meeting of the Waterworks Committee the Surveyor reported that Mr. Baldwin Latham had inspected the proposed new sources of water for the town supply at Scalford and the vicinity. The results of the gauges taken during the last nine months were stated to have been highly satisfactory, and it is confidently anticipated that a more than adequate supply will be forthcoming.

TRURO.—At a monthly meeting of the City Council held last week it was decided to adopt the recommendation of the Chief Inspector of Nuisances, Mr. Herbert E. Bellamy to purchase and maintain their own horses and carts for the purpose of the removal of house refuse and street sweepings. A report was also presented and read by Mr. Bellamy upon the condition of the public wells within the city, and in which he says that out of twenty-three examined only five could be passed as satisfactory, and no less than sixteen if allowed to be continued would be required to be lined with brickwork set in cement, and backed with puddled clay from the top down to the impervious stratum or shelf, and sundry repairs to be done to three, which would amount to about £350. After a long discussion the report was adopted and the amount sanctioned.

Personal.

MR. G. R. GREEN has been appointed Medical Officer of Health for the city of Ripon.

MR. W. K. BAKER has heen appointed Inspector of Nuisances for the borough of Chelmsford.

MR. F. G. SMITH has been appointed Medical Officer of the Stockton workhouse and district.

MR. A. M. WATTS has been appointed Medical Officer for the first district of East Ashford union.

MR. F. A. WINTER has been appointed Inspector of Nuisances for the urban district of East Cowes.

MR. G. HOPE has been appointed Medical Officer of Health for the urban district of Hanwell.

MR. J. WINTER DRYLAND has been reappointed Medical Officer of Health for the urban district of Kettering, at a salary of £50 per annum; and Mr. John Barrit has been reappointed Inspector of Nuisances, at a salary of £120 per annum.

Mr. W. E. James has been appointed Medical Officer for the Mynyddislwyn district of Newport union.

Mr. O. B. Trumper has been appointed Medical Officer of Health for the urban district of Market Rasen.

Dr. Greatbatch has been appointed Medical Officer for the burgh of Montrose in room of Dr. Lawrence.

Mr. H. C. Darby has been appointed Medical Officer of Health for the urban district of Lye and Wollescote.

Mr. Robert Young, the Gas Manager at Laurencekirk, has received the appointment of Gas Manager at Lockerbie.

Mr. W. M'Whirter, M.I.E.E., Aberdeen, has received an appointment in India, to carry out a new system of electrical train signalling.

Mr. T. G. Taylor, Borough Surveyor of Douglas, Isle of Man, has been selected for the vacant post of Surveyor to the Borough of Ramsgate.

Dr. C. B. T. Musgrave has been appointed Medical Officer for the Cromee district, and Mr. H. C. Dent Medical Officer for the Northrepps district of Erpingham union.

Mr. Walter Blackshaw, A.M.I.C.E., has resigned his position as Chief-Assistant in the Croydon Borough Surveyor's Department, and take up a new appointment as Surveyor to the Urban District Council of Cannock.

Sewerage Schemes.

[To Municipal Engineers and Surveyors.—The Editor will be pleased to receive items for publication relating to sewerage schemes projected or inaugurated, together with explanatory diagrams or photographs. The former should be drawn and lettered in black ink.]

Spring Vale sewer, Whitby, is to be extended at a cost of £468.

The Thurnscoe Urban District Council is considering plans for sewage and water schemes.

The Local Government Board has sanctioned the borrowing of £485 for sewerage works at Seaford.

The Andover Corporation has engaged Mr. White, of Oxford, to prepare plans for the drainage scheme.

The Heanor District Council has decided to apply for an additional loan of £2000 to carry out alterations required in the sewerage scheme.

At the last meeting of the Roundhay and Seacroft Rural District Council, the Clerk was instructed to apply to the Local Government Board for permission to borrow £15,000 for sewers and sewage disposal works at Roundhay, and £3840 for sewers and sewage disposal works at Seacroft.

The new sewerage scheme which the Bakewell Rural District Council has decided to construct for Tideswell will cost from £4000 to £4500.

Referring to the borrowing of £3000 by the Yelverton District Council for purposes of sewerage and sewage disposal, the Local Government Board has requested, before granting the application, to be furnished with certain plans.

The Special Committee of the St. Andrews Burgh Commission has appointed a Sub-committee to consult with Mr. Henry Bruce, C.E., as to the construction of an interceptor intended to remedy the complaint as to certain portions of the sewage.

The Chailey Urban District Council has instructed its clerk to make application to the Public Works Loan Commissioners for the balance of the loan of £1300 which they had agreed to advance to the Council in respect of the drainage of the village of Newick.

The scheme for the sewerage of the village of Kibblesworth is now approaching completion. The contract is being carried out by Mr. J. Carrick, of Durham. Hitherto the village has been drained by open brick channels, which were offensive and unsanitary.

At a special meeting of Moffatt Burgh Commissioners held to decide upon one of three systems of sewage purification as reported on by Mr. T. O. Niven, C.E., Glasgow, it was resolved to adopt the system known as Mr. Dibdin's or the Sutton system. The total estimated cost of introducing this system of sewage purification is £2350.

With reference to the application of the Berkhamstead Rural District Council to borrow £11,000 for the works of sewerage and sewage disposal for the parishes of Berkhamstead and Northchurch, the Local Government Board has sanctioned loans of £4928 and £2022 for the proposed new works, and of £2628 and £1072 for the reconstruction of defective sewers.

Important and necessary improvements are being proceeded with in the vicinity of the Marquis's Bridge on the County Down side of the Lagan. An important reclamation of ground has been made, a sea wall being erected that causes the river to flow in its natural bed. In this reclaimed ground, which covers a considerable area, new streets are already laid out for building purposes. Considering the large increase of buildings already completed and the increase of population of Ballynafeigh, it was deemed necessary by the City Council to divert the sewage of that locality from being emptied into the Lagan. At the present time a wonderful change is taking place which will be highly appreciated by the inhabitants whose dwellings border on the Lagan, viz., the making of a large sewer right across the park. This sewer will be joined to the main drainage sewer at Ravenhill-road, the works at present being rapidly proceeded with by the contractor.

A Local Government Board inquiry has been held at Skipton into an application of the Urban District Council to borrow £1200 for the Broughton-road sewerage scheme, and a further application to borrow £400 for a new steam fire engine and appliances. There was no opposition to the applications. The Inspector stated, with respect to the sewerage scheme, that duplicate pumping arrangements would be insisted upon.

The Local Government Board has written the Otley District Council refusing to sanction the loan of £4000 for improving the sewage disposal works, and stating that owing to the admission of trade effluents into the sewers, especially that from the Wharfedale Paper Mills, the disposal works are quite insufficient to deal with the volume of sewage brought to the outfall, and the land in use for the treatment of the effluent is thoroughly water-logged, and at present unfit for the purpose.

The Lizard sewage outfall business being settled, Helston Rural Authority has decided to accept Lord Falmouth's proposals, except the one that the Council should pay the whole of the costs incurred by his lordship's solicitors, who are to be asked the amount of those costs, and what they are for. The Clerk will take steps to borrow a sum not exceeding £500 for carrying out the works, while Lord Robartes and Lord Falmouth are to be appealed to for a contribution towards the expense of the scheme.

A meeting was held at Manchester on Wednesday, the 9th inst., of the Special Sub-committee which was appointed by the Rivers Committee in November last, owing to the rejection of the culvert scheme, to inquire as to the best method of sewage purification. The members of the Sub-Committee have visited a number of towns and inspected various systems of sewage disposal, and it is understood that their report—which was finally approved at Wednesday's meeting—will be, in effect, a recommendation to the City Council to adopt land filtration on what is known as the biological system. There are various estimates of the cost of carrying this out, generally much below the expenditure which the culvert scheme would have involved.

Probably by far the most important public project ever undertaken in New Orleans is the drainage of the city, which is now under way. Five years ago the proposition for a complete drainage system was first broached, and an advisory Drainage Board was created, a preliminary survey made of the city, and a plan of drainage prepared. The present system is very unsatisfactory. It renders the city easily susceptible to rain overflows, makes the soil and the climate damp, it affects public health unfavourably, and increases the death-rate. The Legislature, in response to the prayers of the people, created a Drainage Commission, and gave it full power over the drainage system, with the right to issue bonds. The Drainage Commission advertised the contract, and it is now settled that a company will do the entire work, operating the pumps and other machinery by electricity, for little over £200,000.

The Local Government Board has written the Market Harborough District Council with respect to the application to borrow £3550 for sewerage works at Kibworth, advising the amendment of the scheme in certain details, stipulating for the return of the plans, and an estimate of the cost under the amended scheme; also, that the consent of the railway company be obtained for the construction of the sewer underneath the gasworks.

Lighting.

At a recent meeting of the Glossop Town Council, a notice of motion was given that the Council apply to the Board of Trade for a Provisional Order empowering the Corporation to supply electric light in the borough.

The Lighting Committee of the Sunderland Corporation has decided to recommend the Town Council to apply to the Local Government Board for a loan of £26,000 in connection with the proposed electric lighting extensions.

The Urban District Council of Prestwich has adopted a resolution of the Electric Lighting Committee that application should be made for a Provisional Order empowering the Council to supply electric light within the district.

The question of providing additional gas storage has been under the consideration of the Port Glasgow Town Council. The Gas Committee recommended a proposal for telescoping the present holder, and this has been agreed to, the estimated cost being about £1000.

A letter was read at the Hackney Vestry on Wednesday, the 9th inst., from the Gas Light and Coke Company, intimating that the price of gas will be raised from 2s. 10d. to 3s. per 1000 cubic feet, except that consumed by the street lamps, which will continue at the present rate until further notice. Several members protested against the increase as most unjustifiable and unreasonable.

A meeting of the Greenock Police Board was held recently to consider the report of the Sub-Committee on Electric Lighting. The Committee reported "that Mr. Teague, the expert who had been asked to report on the scheme, was of opinion it would not be necessary for the Board to light up the whole burgh in the meantime, and he recommends that operations be commenced on a moderate scale. He suggests the central site at Hunter-place, part of which is presently used as the depôt for the materials of the Master of the Works Department, and estimates the cost of an installation on that site at about £25,000, exclusive of the cost of the site. The installation proposed to be laid there would be capable of lighting up an area along the main thoroughfare, and including side streets, from Campbell-street on the west to the east side of Victoria Harbour on the east.

At a recent meeting of the Grimsby Town Council, a Committee of twelve members was appointed to consider and report as to the advisability of the purchase by the Corporation of the properties of the Grimsby Waterworks and Gas Companies, and upon what terms and conditions the said properties could be acquired.

All the electric lights at Yarmouth were on Saturday night suddenly extinguished through an explosion in the generating station, where two engines were wrecked through the condensers having been blown out, The street lighting was afterwards restored, but the service to private users, mostly for shops, failed utterly. Some days will be occupied in repairs before the private service can be again available. Traders transacted Saturday night's business with candles and lamps.

A Local Government Board inquiry has been held at Morecambe in reference to two applications made by the District Council for sanction to borrow £1400 for works of water supply, and £10,000 for electric lighting purposes. For the latter purpose a sum of £26,000 had already been borrowed. It was stated that the extra money was required on account of the increasing of the number of arc lamps on the promenade from 75 to 100, and the great demand for electric light at the west end of the town.

Electric lighting is making big strides in North London, and before long nearly all the main roads will be electrically lighted. The number of private consumers is increasing every week, and not a single vestry that has installed the light has failed to extend the system. In Shoreditch it is expected that there will be a profit of £2000 on the year's working, although the loss on the first quarter was £500. Islington shows a profit on revenue account of £4432 for 1897, and in St. Pancras the figures will show an increase of 25 per cent. Although in Hampstead the first fifteen months' working showed a loss of £2916, a profit of over £3000 is estimated for last year. As the profits from gas have heretofore gone into the pockets of private companies, ratepayers will appreciate the success of electric lighting, as the larger the profit the greater will be the relief to the rates.

Obituary.

SIR RICHARD QUAIN, M.D.

One of the most distinguished and popular men of the time has passed away by the death, on Sunday morning, of Sir Richard Quain, M.D.

He had been in ill-health for a long time, and was obliged to undergo two operations. All hope of his recovery had to be abandoned a fortnight ago, and since then his stock of strength gradually ebbed away, until on Saturday night he sank into a comatose state, and died peacefully at six o'clock on Sunday morning, in his eighty-second year. Through the skill of several medical friends (two of whom, Dr. Harold and Mr. Herring, were in constant attendance) he experienced no pain whatever.

Apart from his medical skill, Sir Richard Quain had great humour and charming geniality. He was a close and intimate friend of some of the most brilliant men of the last thirty years and a *persona grata* with Lord Beaconsfield. When the Duke of Fife, as a bachelor, entertained the Prince of Wales at Mar Lodge, no party was complete without Sir Richard Quain, for his presence always ensured any party being a success. He was the kindest friend to journalists, singers, and actors, many of whom he attended with an affectionate solicitude which he could not have exceeded for princes. It was with him a matter of pride that in his long career he never knowingly accepted a fee from a journalist. He constantly used his talents for doing kind deeds, and few who turned to him for help were ever disappointed.

Sir Richard was one of the many distinguished medical men who have been furnished by Ireland. He was born beside the lovely Blackwater, in the county Cork, in 1816, and began life under a surgeon apothecary in Limerick.

Making his way to London, as a young man of twenty, he entered the medical faculty of University College in the year that Queen Victoria came to the throne. During the ensuing half-century his career was one of accumulating fame, and of many professional distinctions.

In 1860 the Queen in Council appointed Mr. Quain a member of the senate of the university in which he had studied, after he had been in early life first house-surgeon and subsequently house-physician to the University College Hospital. He was also made Physician Extraordinary to Her Majesty.

He was a member of the Royal Commission which, in 1865, investigated the rinderpest, his colleagues being Lord Salisbury, Lord Playfair, Lord Spencer, and the late Lord Sherbrooke.

Several learned societies made him a Fellow; Trinity College, Dublin, gave him an hon. M.D.; Edinburgh, an hon. LL.D. He was one of the founders of the Pathological Society, editor of the "Dictionary of Medicine," author of numerous medical works, and had much responsibility for the last two editions of the "British Pharmacopœia"

Correspondence.

We do not in any way hold ourselves responsible for opinions expressed by our correspondents

A ROYAL COMMISSION ON SEWAGE DISPOSAL.

(*To the Editor of* The Sanitary Record.)

Sir,—All who have taken an intelligent interest in the modern attempts at sewage disposal will hail with thankfulness a Royal Commission on the subject. Especially is this the case with those who, like myself, have proved the latent power which undiluted sewage has "to make the desert smile, and the wilderness to rejoice and blossom as the rose." I for one have no fear of the result a Royal Commission will have on the bacterial treatment of sewage—a treatment that aims at solving the pro-

blem without the aid of land—for those who have initiated this method are being led by a way which they do not desire to know, and to see what they have refused to acknowledge before, namely, that it is futile to circumvent a beneficent law of nature by unnatural means.

The bacterial treatment of the waste products of life only need to be stripped of the glamour which is being thrown around it "as a profound new discovery," when it stands out as a perfectly natural method which has been in operation since the dawn of creation. For have not the researches of the agricultural chemist and biologist demonstrated that the fertile soil teems with bacterial life, and, in fact, is living earth, and not dead matter? Also, that it is this living earth which extracts from sewage the noxious matters which it contains, and changes them into luxuriant plant life. Yes, and what seems stranger still, this living earth has the power of destroying disease organisms which are ever present in sewage, and what causes foulness, disease, and death, will, when properly applied to the soil, produce health, life, and a growth so enormous as hardly to be realised.

It is most remarkable that the results of modern science, arrived at most unwillingly and in opposition to the cherished hopes of those who are trying to solve the sewage problem, should at last lead us to see a glimpse of the unsearchable wisdom of the Great Creator in all this, and that we, who cannot create a single atom, can by conforming to the conditions of nature, transform that which is already created, and that which has served its original purpose, into new and living forms of usefulness. This can be accomplished by carrying out the natural law that all that has come from the earth should be returned to it, and that all things that have had life will nourish future life when given fair play, by being placed within reach of the bacteria of the soil under proper conditions.—Yours faithfully,

WILLIAM BOWLER.

Longsight, March 9th.

Notes and Queries.

Subscribers have the privilege of obtaining advice in this column on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed to THE EDITOR, "Notes and Queries," THE SANITARY RECORD, 5, Fetter-lane, London, E.C.]

NOTE.—If an answer be required immediately, a stamped addressed envelope must be enclosed, when we will endeavour to furnish a copy of the answer by post, as owing to the large number of queries received we cannot guarantee the insertion of a reply in the succeeding issue.

994.—INSPECTORS OF FACTORIES: MODE OF APPOINTMENT.—"F. H." writes:—"I am much obliged for your reply to my query. I have obtained, as suggested by you, particulars as to the examinations and appointments, from which I infer that the appointments are competitive. So I am undecided what to do, and shall be obliged if you will favour me with additional information on the subject. I enclose papers received from the Home-office."

Answer.—As we pointed out in our former reply, the appointment of Inspectors is vested in the Home Secretary, and this is borne out by the circulars obtained by our correspondent from the Home-office and submitted to us. Appointments are of two classes:—(1) Male Inspectors of Factories, and (2) Assistants to Inspectors of Factories. The limits of age for the former class are 21 and 30, with an extension up to 38 (*a*) in the case of a person who has been occupied as master, manager, foreman, or workman in a factory or workshop, for at least seven years, and has acquired practical acquaintance with the working of factories and workshop, and (*b*) in the case of a person who may have served as a Factory Inspectors' Assistant with the certificate of the Civil Service Commissioners from a time when he was under 30. The limits of age for Assistants to Inspectors are 21 and 40. The Civil Service Commissioners state that they are authorised by the Secretary of State to make the following announcement:—"Applications for the post of Inspector of Factories or of Assistants to Inspectors of Factories addressed to the Home Secretary will be considered from time to time as occasion may arise or fresh nominations be made. In the event of more than one candidate being nominated for a single vacancy and the examination thus being made competitive, the candidates will be so informed at the time they are nominated." The salary of an Assistant to Inspectors of Factories commences at £100 a year, and rises by annual increments of £5 to £150. The salary of an Inspector of Factories is not stated, but will be found in Whitaker's Almanac for 1898, page 157, and ranges from £200 to £500. The examination fee for Assistants is 10s., and for Inspectors £3. The subjects of examination are as follows:—For Assistants (1) Spelling and handwriting as tested by dictation; (2) arithmetic, first four rules, simple and compound; (3) an elementary knowledge of the principal provisions of the law relating to workshops.

For Inspectors of Factories the subjects are:—(1) Handwriting; (2) spelling; (3) arithmetic, including vulgar and decimal fractions; (4) English composition; (5) theoretical and practical acquaintance with factories and workshops, including a knowledge of their sanitary requirements; (6) applied mechanics, including elementary mechanical drawing; (7) (*a*) the Factory and Workshop Acts administered by H.M. Inspectors of Factories; (*b*) an acquaintance with the history of factory legislation in the United Kingdom.

No person can be appointed Inspector of Factories until the Civil Service Commissioners have issued in his favour a certificate of qualification for the post. Such certificate cannot be issued until the candidate has passed to the satisfaction of the Commissioners in all the subjects specified above. When two or more candidates are nominated to compete for one vacancy the competition will be in the subjects 5, 6, and 7.

If our correspondent desires to obtain a post as Inspector or Assistant he should make written application to the Home Secretary. We must observe that examinations for these appointments do not take place at fixed intervals, but are held from time to time as candidates are nominated by the Home Secretary to fill the vacancies which occur. The application should be written on foolscap paper, and made to the Secretary of State for Home Affairs, Whitehall, S.W. It is often found to be advantageous if a candidate can obtain the aid of a member of Parliament to recommend him to the notice of the Home Secretary.

995.—SWINE: IMPROPERLY KEEPING.—"J. C." writes:—"In my district the inhabitants generally take a delight in keeping animals and domestic fowls. As a rule the structures in which they are kept are built of pieces of timber of all shapes, sizes, and thicknesses, and when constructed they present an unsightly appearance, besides causing a great amount of trouble to the sanitary officials in constantly superintending them. Eighteen months ago I successfully prosecuted four persons for improperly keeping swine, there being defective pavement, absence of drains, and the premises generally being filthy. After the conviction the structures were moved some 40 yards further afield. The same conditions as to drainage and pavement still exist, but the premises are not yet so foul as formerly. I should like to know if the

Sanitary Authority have no supervision over these temporary structures such as would enforce the submission of plans for approval, showing the proposed means of drainage and other necessary provisions before such places can be used for keeping swine? There appears to be two ways of dealing with this class of nuisance, viz.:—Under Secs. 47 and 91 of the Public Health Act, 1875. Is it not more judicious to proceed under the former section?"

Answer.—Such buildings as those referred to are usually exempted from the operation of building bye-laws when they are distant "at least 8ft. from the nearest street and at least 30ft. from the nearest building and from the boundary of any adjoining lands or premises." In urban districts control over the keeping of swine is best exercised by the adoption of bye-laws for the prevention of keeping of animals on any premises so as to be injurious to health. Such bye-laws usually prescribe that swine shall not be kept nor swine's dung deposited within 100ft. of any dwelling-house, and also for the drainage of premises wherein such animals are kept. The effect of the adoption of such bye-laws is that it is not necessary to prove the existence of a nuisance, which is sometimes difficult to establish to the satisfaction of a Court of Summary Jurisdiction. All that is required is to prove that there is a contravention of the bye-laws, and it is not necessary that it should be a nuisance to any person. In the absence of such bye-laws, proceedings should be taken in urban districts under Sec. 47 of the Public Health Act, 1875, against the owner of the swine for keeping them "so as to be a nuisance to any person." It may be observed that the section applies not merely to the keeping of swine in improper places, but to keeping in an improper manner. It is not necessary to prove that the nuisance is also injurious to health.

996.—Footway Gutters: Powers of Urban Authority.—"Furnessia" writes:—"It is the practice here to drain the rain water from down-spouts across the footpaths by means of cross channels, which discharge into the channel at the side of the road. At the present time we make the owners put in iron cross channels, but some years ago stone ones were allowed to be used; the consequence is that some of these are now getting into a bad state of repair and very much worn, which causes water to stand in them in wet weather. I shall be glad if you will let me know through your valuable paper—which I read with interest—who is responsible for replacing the stone channels in cases where the streets have been taken over as public highways. Is it the owner's place to do this as part of the drainage of his property, or should the Council do it, as the footway is part of the highway, and the stone cross channels have been worn away by the traffic over same? As I am about to repair some of the old footpaths, I shall be obliged for advice."

Answer.—The district of our correspondent is that of an Urban Sanitary Authority. Under the provisions of Sec. 74 of the Towns Improvement Clauses Act, 1847, which section is incorporated with the Public Health Act, 1875, by Sec. 160 of the later Act, "the occupier (or owner, as extended by Sec. 160 of the 1875 Act) of every house or building in, adjoining, or near to any street shall, within seven days after service of notice from the Commissioners, put up and keep in good condition a shoot or trough of the whole length of such house or building, and shall connect the same either with a similar shoot on the adjoining house or with a pipe or trunk to be fixed to the front or side of such building from the roof to the ground, to carry the water from the roof thereof in such manner that the water from such house, or any portico or projection therefrom, shall not fall upon the persons passing along the street or flow over the footpath; and in default of compliance with any such order within the period aforesaid such occupier (or owner) shall be liable to a penalty not exceeding 40s. for every day that he shall so make default." We are of opinion that the Urban Authority in the case named by our correspondent may, under the provisions of this section, require the owners to repair or renew the footway gutters or substitute iron gutters for stone ones if such be deemed necessary by the Urban Council.

997.—County Medical Officer of Health: Powers of.—"Sanitas" writes:—"The district of this Authority is an urban one. Recently the County Medical Officer of Health paid an official visit to the town, and subsequently furnished the Corporation with a report on the unsanitary condition of the town; and when this report was discussed at the Council meeting some of the members ridiculed it and persisted in saying that the County Medical Officer had no right to visit the town in his official capacity or send any report thereon. Would you kindly advise whether this contention is correct?"

Answer.—We are not informed whether the district of the Authority referred to is that of a county borough, but assume that such is not the case. The duties and powers of a County Medical Officer of Health are not defined by statute, but are usually prescribed by regulations by the County Council appointing him. He is by such regulations generally required to keep himself informed, and to report to the County Authority, of the sanitary state of the constituent sanitary districts within the county, and as to whether there has been any neglect to properly put in force the Public Health Act, 1875, in any district in the county. Although he has no statutory powers of inspection or interference without the concurrence of the District Authorities, it is, we are of opinion, contemplated by Sec. 19 of the Local Government Act, 1888, that the County Council are enabled to institute such inspection, for Sub-section 2 of Sec. 19 enacts that: "If it appears to the County Council from such report (of a District Medical Officer of Health) that the Public Health Act, 1875, has not been properly put in force within the district to which the report relates, or that any other matter affecting the public health of the district requires to be remedied, the Council may cause a representation to be made to the Local Government Board on the matter." We infer that in the case named the County Medical Officer of Health has been entrusted, in consequence of the neglect of the District Authority, to ascertain whether there has been default in putting into force the provisions of the Public Health Act, 1875, prior to the County Authority causing a representation to be made to the Local Government Board on the matter, and that the information obtained has been furnished to the District Council for their observations thereon. If the District Council failed to give such required observations the County Council will doubtless make a representation to the Local Government Board, under Sec. 299 of the Public Health Act, 1875.

998.—Common Lodging-house: What is a?—"J. C." writes:—"In my district, in the course of a house-to-house inspection, I have met with a number of dwellings in which lodgers of the poorer classes are kept, and as they do not appear to me to come within the definition of common lodging-houses I shall be pleased to have an expression of your valued opinion thereon. In one dwelling-house there are eleven adult inmates, viz., the occupier, his wife, daughter, and eight male lodgers. They occupy six spacious bedrooms with no apparent overcrowding, but enjoy in common the kitchen as a day-room, its content being about 1179 cubic feet. The lodgers, who are strangers to each other pay, 3s. 6d. per week for lodging only, and find their own provisions. They work at a neighbouring ironworks, the last lodger being admitted over six months ago. The house is clean and appears to be well kept. As we have many houses of a similar description in the district, may I ask if you would consider the one in question a common lodging-house requiring registration? Having regard to Section 91, Sub-sec. 5, of the Public Health Act, 1875, are you of

opinion that part of this house is overcrowded, so as to constitute a nuisance?"

Answer.—We are of opinion that the house in question could not be held to be a common lodging-house. We may observe that there is no statutory definition of a common lodging-house, but the Law Officers of the Crown, when consulted as to the meaning of the expression "common lodging-house," advised that it appeared to them to have reference to that class of lodging-houses in which persons of the poorer class are received for short periods, and though strangers to one another are allowed to inhabit one common room. They were also of opinion that it did not include hotels, inns, public houses, or lodgings let to the upper and middle classes. Some assistance is also given as to arriving as to what is a "common lodging-house" by the definition of the term "public lodging-house" in the Towns Improvement Clauses Act, 1847, Sec. 116, which is as follows:—"Every house shall be deemed a public lodging-house within the meaning of this Act in which persons are harboured or lodged for hire for a night or for less than one week at one time, or any part of which is let for any term less than a week."

We do not think under the circumstances named, that a conviction could be obtained against the occupier for a contravention of the provisions of Sec. 91, Sub-sec. 5, of the Act of 1875, for overcrowding.

999.—Refuse Removal: Duty of Local Authority.—"J. W." writes:—"In the centre of my district, which is a rural one, is the market town, having a population of about 900, which has a sewerage system and a proper water supply. There is great difficulty in dealing with vegetable refuse and contents of privies, middens, and receptacles, for want of a suitable tip. Is it the duty of the Council to provide a site for the disposal of these matters? Is it also their duty to provide a site for the disposal of vegetable and fish refuse from those dealing in vegetables and fish?"

Answer.—The Rural District Council, as the Sanitary Authority, should, we are of opinion, provide a means of disposal for the matters removed from privies and ashpits. If this is not done it is highly probable that the Local Government Board will, if a complaint be made to them under Sec. 299 of the Act, by order require them to undertake or contract for the removal of house refuse from premises, and the cleansing of earth-closets, privies, and ashpits, for the town, under Sec. 42 of the Act of 1875. Vegetable and other refuse from shops is trade refuse, which the Local Authority cannot be required to remove or provide means for its disposal.

1000.—Water-closets without Proper Means of Flushing: Procedure to Enforce.—"J. W." writes:—"Many houses in an urban district have one or more sufficient water-closets internally, but have an external water-closet in addition without any proper means of flushing. Does Sec. 36 of the Public Health Act, 1875, apply to these outside water-closets under such circumstances, or is it necessary for the Urban Council to frame bye-laws as to keeping water-closets flushed with water, under the Public Health Acts (Amendment) Act, 1890? Or what other course is it necessary to take?"

Answer.—Inasmuch as the houses are already provided with one sufficient water-closet, we are of opinion that the provisions of Sec. 36 of the Act of 1875, will not apply in the cases named by our correspondent. If the water-closets are, owing to the absence of proper means of flushing, a nuisance or injurious to health, the Local Authority may institute proceedings against the owners under Secs. 41 or 94 of the Act of 1875. Where, however, the Public Health Acts (Amendment) Act, 1890, has been adopted, it will generally be found more advantageous to frame bye-laws under Sec. 23 of that Act, as to the keeping water-closets supplied with sufficient water for flushing, and proceed against the owner under the provisions of these bye-laws. It may be observed that such bye-laws apply both to old and new buildings. Model Bye-laws under the section named may be obtained from the Local Government Board, or from Messrs. Knight and Co., 90, Fleet-street, E.C.

Contracts Open.

The dates given below are the latest up to which tenders can be received.

Great Wakering (Essex). — March 21st. — Scavenging.—Mr. Frederic Gregson, Southend-on-Sea.

Hull. — March 21st. — Scavenging. — Mr. J. P. Chatham, clerk, Lincoln's-inn-buildings, Hull.

London, N. — March 21st. — Sewers. — Mr. E. J. Lovegrove, C.E., engineer to the Council, Southwood-lane, Highgate, N.

Spennymoor.—March 21st.—Scavenging, &c.—Mr. G. W. Rogers, surveyor, Spennymoor.

Wakefield.—March 21st.—Sewerage Works.—Mr. R. Porter, city engineer, Town Hall, Wakefield.

Alford (Lincs).—March 22nd.—Scavenging.—Mr. J. E. H. Sergeant, clerk to the Urban District Council.

All Sanitary & Scientific Publications.

SCHERING'S NEW DIETETIC.

This is a new albumen preparation for domestic use. Its constituents, similar to milk, especially Human Milk, give it a peculiar value.

SANOSE

SANOSE is an odourless and tasteless white powder, forming an emulsion when stirred in water.
THE MEDICAL PROFESSION strongly recommends it in cases of Anæmia, Dyspeptic troubles, Consumption, and in Cachectic Women.

For literature see "THE THERAPIST," November, 1897, and January, 1898.

Price 1s. per ounce; 3s. 6d. per 4 ounces.

Apply to all Chemists and Druggists, or to **A. & M. ZIMMERMANN**, 9-10, St. Mary-at-Hill, London. E.C.

SITUATIONS.

VACANT.

☞ *Advertisements of Situations Vacant are inserted at the rate of Sixpence per line (prepaid), minimum three lines — eight words to line. Special rates for a series.*

WANTED.

THE SANITARY RECORD *will be found an excellent medium for those who are desirous of seeking Situations in the Offices of Surveyors, Sanitary Inspectors, Sanitary Engineers, Architects, &c. The charge for such advertisements (prepaid) is Sixpence per line. Minimum three lines—eight words to the line.*

☞ **Advertisements for this Department must reach us by Tuesday morning in each week, at latest.**

SANITARY INSTITUTE EXAMINATIONS.

TUITION BY CORRESPONDENCE.

An Engineer and Surveyor (Mem. San. Inst.), Certificated Surveyor and Inspector, prepares students for these Exams. by Correspondence through the post.

Fees strictly moderate. Cramming studiously avoided.

The course of tuition is arranged so as not only to qualify the student for passing the exams., but what is of equal importance, viz., that he may become a thoroughly efficient Inspector.

On successfully passing the exams., all possible assistance and advice is given to help forward intending candidates for public offices.

Many of my old pupils are now filling positions with salaries of over £120 a year.

For terms, &c., address "C. E.," care SANITARY RECORD, 5. Fetter-lane, London, E.C.

SANITARY ASSOCIATION OF SCOTLAND

EXAMINATIONS IN SANITARY SCIENCE.

Examinations for Certificates of Competency in Sanitary Science are held each year as follows, viz.:—In Glasgow in April, in Edinburgh in October, and at such other time and place as the Board of Examiners may determine.

Entrance Fee £2 2s.

For further particulars apply to

GEORGE MIDDLETON, M.A., LL.B.,
Writer, 92, Bath Street, Glasgow,
Secretary to the Board of Examiners.

A Stamped Addressed Envelope must accompany all letters requiring an answer.

SANITARY INSTITUTE EXAMINATIONS.

SPECIAL Corresponding Classes for the **Practical Sanitary Science,** and **Sanitary Inspectors' Examinations** of the **Sanitary Institute, 1898,** conducted by a gentleman holding appointments as Urban District Council Engineer and Sanitary Inspector, holder of three certificates from the Sanitary Institute, First-class Honour Medallist Hygiene, &c. Hundreds of successes.—For all particulars, testimonials, &c., apply Mem. San. Inst., Office of THE SANITARY RECORD, 5, Fetter-lane, London E.C.

OFFICIAL ADVERTISEMENT.

COUNTY BOROUGH of SUNDERLAND.

INSPECTOR OF HOUSE DRAINS AND SANITARY FITTINGS.

WANTED, by the Corporation of Sunderland, an INSPECTOR, to superintend the construction and perform the testing of House Drains and Sanitary Fittings.

Salary £130 per annum, increasing by £10 yearly until £150 per annum be reached.

Candidates must have had a thoroughly practical experience in works of sewerage, drainage, and sanitary plumbing, and must hold the certificate of the Sanitary Institute.

The person appointed will be required to devote his whole time to the duties of the office, and may, in addition to the foregoing duties, be required to discharge those of an Inspector of Nuisances.

Personal canvassing for the appointment will be a disqualification.

Applications, in the handwriting of the candidates, stating age, residence, past and present occupation, accompanied by copies of not more than six testimonials of recent date, must be delivered to me on or before Thursday, the 31st March instant, endorsed, "Inspector of House Drains, &c."

By order,
FRAS. M. BOWEY,
Town Clerk.

Town Hall, Sunderland,
14th March, 1898.

COUNTY BOROUGH of SUNDERLAND.

INSPECTOR OF SEWERS.

WANTED, by the Corporation of Sunderland, an INSPECTOR of SEWERS.

Salary £140 per annum, increasing by £10 yearly until £180 per annum be reached.

Duties will include the supervision of the laying of all new sewers, and the relaying, repair, inspection, cleansing, and flushing of all existing sewers, &c.

Candidates must have had a thoroughly practical experience in works of sewerage and drainage.

The person appointed will be required to devote the whole of his time to the duties of the office.

Personal canvassing for the appointment will be a disqualification.

Applications, in the handwriting of the candidates, stating age, residence, past and present occupation, accompanied by copies of not more than six testimonials of recent date, must be delivered to me on before Thursday, the 31st March instant, endorsed, "Inspector of Sewers."

By order,
FRAS. M. BOWEY,
Town Clerk.

Town Hall, Sunderland,
14th March, 1898.

"THE CHEMICAL AND BIOLOGICAL EXAMINATION OF WATER,"

BY

C. G. MOOR, M.A., F.C.S.

These Articles, which have been expecially written for THE SANITARY RECORD by Mr. Moor, will be fully illustrated, and will embody the results of the latest researches on this all-important subject.

The writer holds a unique reputation as joint author (with Mr. T. H. Pearmain) of "Applied Bacteriology" and "Aids to the Study of Bacteriology," both of which works have received high encomiums from the *Lancet*, the *British Medical Journal*, the *Chemical News*, &c., and we have no hesitation in commending this new series to the notice of all Public Bodies who are interested in the purity of public water supplies.

A

New Series of Articles

BY

W. J. DIBDIN, F.I.C., F.C.S.,

Late Chemist to the London County Council, Author of "The Purification of Sewage and Water," &c.,

WILL COMMENCE IN

The Sanitary Record

AT AN EARLY DATE.

Mr. Dibdin has chosen for his subject—

"LIME MORTAR AND CEMENT: Their Composition and Analysis,"

And the Articles will prove invaluable to Surveyors, Municipal Engineers, &c.

The date of publication will be duly announced in this column.

NOTICES.

ANNUAL SUBSCRIPTIONS.— The Annual Subscription to "The Sanitary Record," paid in advance, is 10s. *This includes postage, and a Copy of the Diary, post free.*

SUBSCRIBERS RESIDING in SCOTLAND and IRELAND are requested to pay by P.O. and NOT *by cheque. If cheques* BE *sent they must be drawn for* 10s. 6d

MSS. cannot be returned unless accompanied by a stamped directed envelope.

Advertisements cannot be inserted unless received before Four o'clock on the TUESDAY of each week.

All communications should be addressed to the EDITOR, at 5, *FETTER LANE, London, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, Ld.*

NOTICE.—On and after 31st March next the Annual Subscription to this Journal will be raised to 12s. 6d. to all NEW Subscribers. NO ADVANCE will be made to our friends whose names are entered on our Subscription list prior to that date, so long as they continue to subscribe.

THE

Sanitary Record,

MARCH 25, 1898.

Notes.

The Plague in India.

THERE was a slight subsidence in the mortality from the plague in Bombay last week, and for that little we have to be thankful. The official returns were 1059 deaths due to plague, and 2137 deaths from all causes, the general death-rate being 133·7 per 1000; but as the returns cannot be complete owing to the opposition of the natives, the true figures are probably very much higher. There is a further telegram, stating that

the city is now quiet; that about 200 arrests were made in connection with the riots, and that the dock labourers on strike have not yet returned to work. That is the gist of this week's news. It is brief; but how it tells of the state of tension in which the rulers of the city must be living. Imagine for a moment such a death-rate in London; what a panic there would be! And yet in Bombay the Sanitary Authorities have not only to witness this terrible mortality, not merely to carry on a deadly struggle with this awful epidemic; but at the same time to combat deep-seated religious and racial antipathies, which make the problem they have to face one of enormous complexity.

The Gravity of the Situation.

In connection with this subject, we would call our readers' attention to a very powerful article in the *Spectator* of the 12th inst., in which the writer draws a very vivid picture of the disastrous state of affairs in the great Indian city, and graphically describes the spirit of discontent and disaffection with which the vast population is at present seething, in consequence of the conflict between the religious traditions and beliefs of the East and our Western notions of the paramount importance of sanitation. It is difficult for us to appreciate to the full the gravity of the situation on account of our imperfect understanding of Oriental ideas; but it is undoubtedly very serious. So bitter, indeed, is the feeling against the measures of the Plague Committee—measures which in the eyes of Hindoos and Mohammedans alike are, in their interference with women and the examination of the dead, nothing short of desecration—that it is not at all impossible that a much more terrible explosion than the one which caused such alarm a fortnight ago might occur any day; and who can tell where it might stop? When the religious fanaticism of the East is once set ablaze, the fear of death is as naught, and it must not be forgotten that we are but a handful of Englishmen in the midst of a city of 900,000 inhabitants.

What is to be Done?

The *Spectator* discusses various alternative methods of dealing with the epidemic, other than that which is at present being carried out with such doubtful success. One is so drastic and even desperate in character that it is easy to understand that the Authorities should shrink from its adoption, to order the removal of the entire population for a time to the mainland, and to cleanse the infected city by fire. And yet the writer believes that the natives would obey such an order with almost stoical content. Another suggestion—and it is singular to think that it also would be acceptable, and perhaps popular—is to suspend all sanitary measures, and allow the plague to run its course until it has killed out all who are liable to its ravages. But that is an idea that would be utterly abhorrent to our notions, however it might chime in with those of the native mind, for it is our plain duty not merely to save the city despite of itself, but to see that the limits of the epidemic are not allowed to extend. If we were to fail in this duty we should incur a grave responsibility to the rest of mankind.

The "Spectator's" Last Course.

A third alternative suggested by the *Spectator* is, if practicable, "to consult the best moolahs and pundits as to the rules which really affect religious faith or the Indian ideas of honour, to withdraw these, and to devote all strength and attention to the thorough cleansing of the city, re-making all drains, opening all quarters impervious to the wind from the sea, burning the floor of the streets, exterminating all rats, closing all chawls—the vast tenement houses with five hundred inhabitants, which are packed like sardine boxes—and burning down remorselessly every house in which an inhabitant has died of the plague." The great objection to the present examination and segregation measures is that they are opposed to all the religious instincts of the people; the Mohammedans, indeed, declare that they are contrary to the precepts of Islam, and nothing can be more dangerous than to persist in a course that has this tendency. Even the native gentlemen of position and influence now refuse any longer to co-operate with the Plague Committee, and that means that the work has to be left entirely to Europeans, who are already in bad odour. The populace prefer to die of disease rather than have their religious ideas violated. There is a touch of irony in the *Spectator's* concluding remark on the lamentable necessity of "killing her Majesty's subjects with bullets in order to persuade them not to suffer themselves to be killed by buboes."

The Small-pox at Middlesbrough.

A recrudescence of the epidemic of small-pox in Middlesbrough has for some time been looked for, and unfortunately these anticipations have been realised, though the revival has not been quite so bad as was feared. Still, after the extremely low number to which the notifications were reduced, it is mortifying to see the number again on the increase. The figures for last week were three new cases on the 13th inst. (the lowest yet recorded), nine on the 14th, sixteen on the 15th, twenty-one on the 16th, sixteen on the 17th, and twenty on the 18th; the total number of cases up till the last-mentioned date being 1012, of which 124 have been fatal, so that during the course of the week we are able to trace a steady increase in the number of cases; and it is further to be noted that nearly all the new cases are from fresh centres. The Authorities believe, however, that the worst is now over. Though the epidemic continues obstinately to linger, the machinery for coping with it is in good working order, the hospital accommodation is ample, and the means of isolating patients excellent. A large number of patients have recently been discharged from hospital as cured, and of those still remaining—about 400—most are convalescent, the number of dangerous cases being very small.

The Vaccination Bill.

The introduction by Mr. Chaplin of the Vaccination Bill last week brings us at length within sight of what we may hope will prove a settlement of most of our troubles connected with small-pox and vaccination. As long as there are hardships in the administration of the law of which anti-vaccinators may

reasonably complain there will continue to be resistance, and lamentable outbreaks, such as that which is still rife at Middlesbrough and the still more dreadful one at Gloucester a short time back, may be expected to recur. The fact that most of their objections to vaccination are founded on fallacies and delusions does not shake the faith of anti-vaccinators in their cause. Their position has been argued with vigour and ability in a pamphlet recently published by so illustrious a scientist as Dr. Russel Wallace, of Darwinian fame. But, however eminent Dr. Wallace may be as a biologist, we are not aware that on this subject he is entitled to speak with any peculiar authority; and therefore, when his distinguished name is triumphantly appealed to by anti-vaccinators, they forget that he cannot claim in this field the weight attaching to a specialist, all the authority of medical opinion being, indeed, on the other side.

The Groundwork of the New Proposals.

Turning now to the proposals that have been placed before Parliament, we find that in the main, as was expected, they follow on the lines of the recommendations of the Royal Commission; and as they undoubtedly remove the principal grievances alleged by the anti-vaccinators, we may hope to see vaccination become practically universal. The proposals are based upon the important scientific discovery which Mr. Chaplin spoke of as one that would probably revolutionise the whole system of vaccination in this country—the preservation of lymph in glycerine. It has been established that this mode of treatment has the effect of destroying all extraneous organisms and noxious germs, without impairing the active qualities of the lymph; and further, the glycerinated lymph can be made in large quantities, and may be preserved for a considerable time. Now, this at once removes the prime difficulty with regard to arm-to-arm vaccination, for the Local Government Board, in compliance with the recommendation of the Commission that calf lymph should be placed within the reach of all, have acquired the necessary accommodation for preparing the lymph, and are making arrangements to supply it as required.

The Provisions of the Bill.

The great objection to compulsory vaccination being, therefore, done away with, vaccination is to continue to be compulsory, but only with calf lymph. Arm-to-arm vaccination will practically cease to be. That, in itself, is a great improvement in the law, and should go far to meeting the scruples of anti-vaccinators, as they will no longer be able to plead that vaccination is the means of transmitting disease. Then the next provision, whereby the public vaccinator will have to attend the child in its own home, as is already done in Scotland, instead of compelling it to be brought to the vaccinating institution, will also be welcomed as a most salutary reform. The third important change in the law is that the period within which a child must be vaccinated is to be extended from three months to twelve months, there being a greater immunity from the risks of vaccination at the more advanced age. Finally, cumulative penalties for non-compliance are to be abolished. The recommendation of the Commission that those who have conscientious objections to vaccination, and make a statutory declaration to that effect, should be exempted, is rightly thought by the Government to be merely opening the door to evasion of the law, and so the penalties are to be retained.

Other Sanitary Measures in Parliament.

Altogether, the week in Parliament has seen quite a creditable share of sanitary legislation. The most important measure has, of course, been the Vaccination Bill, whose prospects of becoming law this session are, we should think, pretty safe, judging from the extremely favourable reception it received from all parts of the House. We have besides to chronicle the introduction once more of the perennial Plumbers' Registration Bill. Let us hope that a better fate is in store for it this year than it has met with in previous sessions. The Rivers Pollution Prevention Bill has also been brought forward for second reading and adjourned; the main object of the Bill being to bring the general law into harmony with what it is in Yorkshire and Lancashire, by enabling Municipal and County Authorities to appoint joint committees to deal with the pollution of rivers in their respective districts. The measure is opposed on the ground that it will prevent Corporations and other Authorities from carrying out important drainage undertakings, but we understand that its underlying principle is viewed with favour by the Government.

Life of Pasteur.

To those who would wish to obtain in a concise and popular form a comprehensive view of the services rendered to science by Pasteur, and of his work in connection with micro-organisms and their effect on man and the lower animals, we would recommend a perusal of the biography published by Messrs. Cassell and Co., in the "Century Science Series." The authors of the book are Dr. and Mrs. Percy Frankland, and they have achieved a considerable measure of success in their undertaking. The results of Pasteur's researches have entered so largely into the modern biological study of disease that it would be well that all who take an interest in the progress of sanitary science should acquaint themselves with the nature of his work, and for this purpose no better means can be afforded than such a popular and well-written handbook as the present publication.

New Methods of Fighting Infection.

Dr. Waldo has performed a public service in the report he has just presented to his Vestry, with regard to the importance of making scientific investigations in doubtful cases of typhoid and diphtheria. In it he emphasises the importance of a threefold bacteriological examination, viz., at the first signs of throat trouble; then, should it prove to be diphtheria, during and after the attack. These investigations, of course, are most valuable in ill-defined attacks. "No one," says Dr. Waldo, "who is skilled in practical medicine could fail to recognise at a glance a well-marked case of either

diphtheria or of typhoid fever. The most experienced medical man in the world, however, will be undecided for a time in a certain proportion of attacks of both these maladies. The bacteriological method would therefore be of value in settling differences of opinion between medical men, and in the case of typhoid would at once determine the proper and only safe line of treatment." The methods of testing are described by Dr. Waldo, together with the means to be employed in the collection of specimens; and the probable cost is put down at from 2s. 6d. to 3s. 6d. per examination; that is, when the necessary outfit has been provided.

Dr. Waldo's Conclusions.

A BRIEF review is made of the practice prevailing in other metropolitan districts; also in the provinces and the United States. The report closes with a statement of the conclusions arrived at by Dr. Waldo, as a result of his investigations. Briefly these are:—(1) That it is of great value from a practical standpoint to detect diphtheria and typhoid fever with certainty, especially in the early and the late stages. In both cases the method may be now and then essential in the prevention of the spread of the disease. (2) That the benefit will be both individual and general—(1) Individual, in the determination of doubtful cases and of the proper course of treatment, and in saving him from unnecessary exposure. (2) General (*a*), in the detection of cases, and so of indicating the need of isolation and disinfection; (*b*) in preventing uncured cases in children from returning to school and there becoming fresh centres of infection. (3) That the possibility of such detection is now rendered scientifically certain by means of a bacteriological examination of the secretions of diphtheria and of the blood of patients suffering from typhoid fever. (4) That the actual cost of the Vestry would be small in comparison with the gain to patients and the prevention of the spread of disease. (5) That, so far as he has been able to learn, the experience of those Sanitary Authorities who have adopted the tests has been satisfactory, although perhaps medical men have not availed themselves of the proffered opportunities so generally as had been anticipated. (6) That in his opinion the adoption of both tests would be of distinct value to the sanitary administration of the district of St. George the Martyr. We understand the report has been referred to the Health Committee of the Vestry, not, we trust, to be "pigeon-holed."

The Policy of Supression.

WE make this last remark advisedly, for it would appear that the St. George's Vestry has resolved to make itself celebrated for the manner in which it treats its officers' reports. Last year our readers will remember an effort was made to suppress Dr. Waldo's annual report, and it seems likely that the same course will be again attempted. The method adopted, however, is more ingenious. We understand that 500 copies of this report have been printed, but for the present only sixty copies are available, that is one copy for each member of the Vestry; the remainder are to be carefully packed up until the annual report of the Vestry shall have been prepared and printed, when it will be bound up with the latter. But months must elapse—that is, if we take former years as a precedent—before this is accomplished. It is not surprising that many think the report contains a further record of "dark places" in Southwark; and that the real reason for the policy of suppression is a lack of willingness on the part of the Vestry to deal with the crying evils of the district. The members will waste whole evenings in discussing "points of order" and "abstract theories"; but no time can be found to perform the proper duties of a public body, viz., administer the law and support its officers in working to promote the health and well-being of the inhabitants. And this, we are told, is one of the "most advanced" Vestries in London.

Sewage Purification.

THE correspondence on this subject at present being carried on in our columns increases in interest as it progresses. It is remarkable how the champions of particular processes are able to prove, "beyond the shadow of doubt," that their own especial method transcends all others in efficiency and economy. But we are gaining knowledge. The publication of results actually obtained will enable impartial observers to judge the advantages to be secured by the adoption of newer systems. And, further, that the nature of the soil and geographical position of each district will still help to make or mar any scheme. Of one thing we are assured, finality is not yet within sight, but the accumulation of facts, such as are forthcoming in our columns from time to time, will enable the present generation to make infinitely better provision for the disposal of its sewage than was possible even a decade ago.

Abatement of Smoke Nuisances.

IN proceedings by a Sanitary Authority to enforce the abatement of a nuisanse by smoke from factory chimneys, it is not necessary that the Authority should describe in the statutory notice to the person in default what works are necessary to be done in order to abate the alleged nuisance. Such was the decision in the Queen's Bench Divisional Court, on January 20th last, in Millard *v.* Wastall, 62 J.P. 135; and this decision will be of interest to many, inasmuch as it has been frequently supposed that in such proceedings the Local Authority should state in their notice what special works were necessary. The case referred to was an appeal from the Justices in and for the Borough of Ramsgate, who had dismissed the complaint on the ground that the notice of the Authority was insufficient, because it did not specify the works required to be done to abate the alleged nuisance. The appeal of the Local Authority was allowed, Mr. Justice North observing that it was not necessary for the Authority to invent works to be done by the persons by whom nuisances are required to be abated. In many cases such as the present no works were necessary; all that was required was that the respondent should refrain from using such coal as caused the emission of black smoke from his chimney. Justice Lawrance also observed that no works were necessary to be done in the case. It was much the same as if a nuisance was caused by keeping pigs; the owner must either keep the styes clean or remove the pigs.

NOTES ON
PRACTICAL SANITARY SCIENCE.

By WILLIAM H. MAXWELL.

Assistant Engineer and Surveyor, Leyton Urban District Council, Author of "Drainage Work and Sanitary Fittings," "Ventilation Heating, and Lighting," &c., Certificates of the Association of Municipal and County Engineers, and Sanitary Institute.

No. 54.—REFUSE DESTRUCTORS.

(*Continued from page 277.*)

"*Steam-raising value of the Refuse and Sewage Cake.*—Duration of trial, 10 a.m. to 10 p.m., March 30th, 1897 = 12 hours. Number of cells of destructor in use, 4.

Detailed Results of Trial.

	tons. cwt. qr.	lbs.
Weight of house refuse consumed	22 5 0 =	49 840
Weight of sewage cake consumed	11 4 1 =	25,116
Total weight of material burnt	33 9 1 =	74,956
Proportion of house refuse to sewage cake	100 : 50·4 =	2 : 1 (nearly)
Average weight of material burnt per cell per hour...	... ...	1,561
Total weight of clinker produced	9 16 2 =	22,008
Proportion of clinker produced to material burnt	... ...	29·4 per cent.
Average steam pressure in boilers	... ...	105
Average temperature of feed-water	... ...	65 deg. Fah.
Weight of water evaporated ...	3192 gals. =	31,920
Weight of water evaporated per hour	... ...	2,660
Weight of water evaporated per lb. of material burnt	... ...	0·426

Corresponding with :—

Weight of water evaporated per lb. of material burnt from and at 212 deg. Fah.	... ...	0·597
Average pressure of air in ashpit	... ...	2 in. of water.

"The extremely low quality of the material consumed (poor house refuse and wet sewage cake) is indicated by the small quantity of water evaporated per pound of fuel (0·426 lb.). In spite of this, the total power produced was considerable; taking the total weight of water evaporated as 31,920 lb., and assuming an average consumption of 20 lb. of water per indicated horse-power, the horse-power available would be 133 indicated horse-power; the equivalent amount of steam coal which would be required to obtain this result is 1¾ tons, representing a cost of £1 11s. 6d., assuming the price of coal to be 18s. per ton delivered at the works.

"The total heat available was more than sufficient to heat the boilers, and these in their turn supplied more steam than was required for the needs of the works, which was served by a 45-horse power engine in the sewage works, and by a 12-horse power engine in the portion occupied by the destructors. A smaller engine drove two fans delivering air to the ashpits of the cells, a dynamo lighting the works and a steam hoist for raising the sewage to the charging floor, and a feed-water pumping engine was also provided with steam from the boilers. The larger engine drove a pump lifting sewage from low to high level, an air compressor for the filter press, and all minor plant in the sewage works.

"*Completeness of Destruction of Refuse.*—During the trial attention was specially directed to the question as to how far the destructor accomplished its work in consuming the wet and objectionable refuse supplied to it in such a manner as to leave nothing but innocuous products. This portion of the inquiry appears to us to be of fundamental importance, in that complete combustion of noxious and putrescent refuse is of greater moment than is the production of power as an incident in its consumption.

"The ultimate materials constituting the output of the destructor are clinker and gaseous products of combustion; both should be as fully oxidised as possible. Accordingly, analyses of the clinker and gases were made with the following results:—

"(I.) *Clinker.*—The quantity of unburnt carbonaceous matter was determined, carbon 2·10 per cent. The amount of combustible material left in the clinker is therefore extremely small; moreover, it is present as well-charred particles, and is no more objectionable than that commonly present in furnace ashes.

(II.) *Gaseous Products of Combustion.*—Samples were taken both from the combustion chamber of one of the destructor cells and from the boiler flues at the point where they were connected with the underground flue leading to the chimney.

A.—*Gases from Combustion Chamber.*

	Percentage by Volume. 1.	2.
Carbonic anhydride (CO^2) ...	6·9	6·7
Carbon monoxide (CO)	Nil	Nil
Oxygen (O)	12·9	12·8
Nitrogen (N)	80·2	80·5
	100·0	100·0
Corresponding with free air ...	61·4	61·0

B.—*Gases from Boiler Flue.*

	Percentage by volume. 1.	2.	3.	4.	5.
Carbonic anhydride (CO^2)	2·7	4·2	5·0	3·6	4·9
Carbon monoxide (CO) ...	Nil	Nil	0·4	Nil	0·2
Oxygen (O)...	17·2	14·8	14·5	15·9	14·4
Nitrogen (N)	80·1	81·0	80·1	80·5	80·5
	100·0	100·0	100·0	100·0	100·0
Corresponding with free air	81·9	70·5	69·0	75·7	68·6

"From these figures it is evident that substantially complete combustion is effected, carbon monoxide (a product of incomplete combustion) being usually absent; and, when present, existing only in negligible quantity in the flue gases. That the combustion was thorough was further proved by frequent observation of the smell of the flue gases; they were found to be free from offensive odour, and to contain no evil-smelling product of destructive distillation or imperfect oxidation. This is of importance, because the consumption of wet refuse is likely to give rise to objectionable gaseous products, unless steps are taken (as in this case) to oxidise the products thoroughly before they pass into the chimney flue.

"On account of this fact it is desirable that there should be an ample supply of air, over and above the calculated quantity necessary for the complete oxidation of the carbonaceous matter. In the case of the samples examined this condition is fulfilled, inasmuch as they contain from 61 per cent. to 81·9 per cent. of free air. It is possible that it may be found practicable somewhat to diminish this large excess of air, without impairing the com-

pleteness of combustion, and with a gain in efficiency in heating the boilers. At present, however, the total heat available is so much greater than that which can be usefully employed, that this increase of efficiency is of no immediate importance.

"*Retention of Dust by Destructor.*—Not only is it necessary that the products of combustion from an efficient destructor should be fully oxidised, but it is also highly desirable that they should be as free as possible from dust and smoke.

"The behaviour of the destructor in this respect was ascertained by filtering a known volume of gas drawn from the combustion chamber, and determining the weight of dust thus separated. The quantity found was:—Dust per cubic foot of gas from combustion chamber, 0·18 grain.

"The amount is, therefore, inconsiderable, even at a point so close to the grate as to allow but little time for the deposition of any suspended matter which might be scattered by the blast of air supplied to the ashpit. Many larger particles of slag (as distinct from fine dust) passed over into the combustion chamber in a state of incandescence. These being in a semi-fused state, adhered to the walls of the chamber, and formed a protective coating on the brickwork against injury either by heat or attrition.

"A trial was also made of the gases passing from the boiler flue to the chimney. In this case the quantity of dust was found too small to estimate.

"Observation of the smoke from the chimney, made at frequent intervals during the trial, showed that the amount emitted was unusually small. It was light brown in colour, and was readily dissipated within a short distance of the mouth of the chimney.

"Considering these facts conjointly, it is evident that during the trial almost complete retention of dust was effected.

"*Temperature of Combustion Chamber.*—The temperature of the combustion chamber when the charge was burning freely was determined and found to be:—

850 deg. Cent. = 1562 deg. Fah.

"This corresponds with a moderate red heat, and is sufficient to complete the combustion of any unburnt products escaping from the grate.

"Naturally, if refuse only of fair average quality was consumed, the heat would be much greater—probably more than 2000 deg. Fah.

"*Temperature of the Flue Gases.*—Observation of the temperature of the gases in the underground flue leading to the chimney was made at intervals during the trial. It was found to fluctuate somewhat according to the stage of firing the cells; the temperatures taken are as follows:—

No. of Observation.	Temperature of the Flue Gases.			
1	230 deg. Cent.	=	446 deg. Fah.	
2	320 ,,	=	608	,,
3	250 ,,	=	482	,,
4	270 ,,	=	518	,,
5	238 ,,	=	460	,,
6	227 ,,	=	440	,,

"The comparatively high temperature of the flue gases is due to the fact that during the trial more heat was being produced by the destructor than could be absorbed by the boilers, the furnaces being indeed capable of generating a good deal more power had a third boiler been available. The two boilers in use were blowing off at 110 lb. pressure throughout the test.

"*Examination when Cold.*—We examined one of the cells in its cold condition, and were unable to discover any signs of wear or abrasion.

"*Conclusions.*—From a consideration of the results of this trial we have arrived at the following conclusions:—

"(1) The destructor is capable of consuming wet sewage-cake, and house refuse of poor character in a complete and satisfactory manner.

"(2) The oxidation of the combustible matter in the material fed into the destructor is complete, and the gaseous products of combustion are inoffensive.

"(3) The gaseous products of combustion are sensibly free from any suspended matter by the time they pass into the flue to the chimney.

"(4) The clinker is well burnt and free from offensive half-charred carbonaceous matter.

"(5) Even when working with a wet sewage-cake, and poor house refuse, the destructor generates more heat than can be used with the present plant at Leyton.

"We therefore consider that this destructor provides an efficient and economical method of destroying the refuse of towns without injury to the neighbourhood. So far as we are aware, it is the only form of furnace yet adopted capable of burning a considerable proportion of sewage sludge—even when containing, as in this case, a high percentage of moisture."

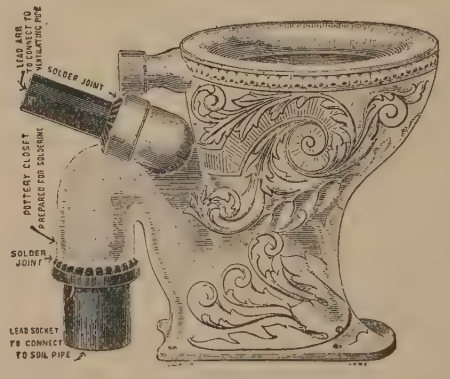
THE SANITATION OF DOMESTIC BUILDINGS.

By Frank Latham, C.E., M. San. Inst., &c., Assistant Surveyor, Borough of Margate.

CHAPTER VI.

Section 1. (*continued*).

Some of the principal joints made for joining water-closets to soil pipes are executed in the following manner:—Dent and Hellyer's closets



LEAD ARM TO BE BURNT TO EARTHING PIPE
SOLDER JOINT
POTTERY CLOSET PREPARED FOR SOLDERING
SOLDER JOINT
LEAD SOCKET TO CONNECT TO SOIL PIPE

Fig. 59.

are, as a rule, specially arranged to meet the difficulty of forming a proper joint. The outlet pipe of closet is of lead, flanged, and bolted to the water-closet trap below the water-line, so that if any leakage takes place it would immediately show itself (Fig. 59). This provision enables a proper

wiped joint being made between the lead outlet and soil pipe branch.

Doulton's patent Metallo Keramic joint (Figs. 59

Fig. 59 (Section).

and 60), is always adopted by the author with their closets, is a lead out-go pipe jointed to the earthenware—a joint which is perfectly se-

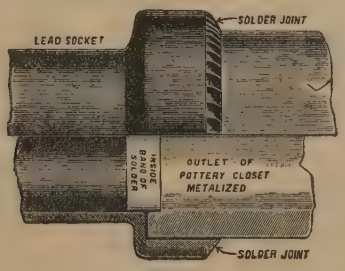


Fig. 60.

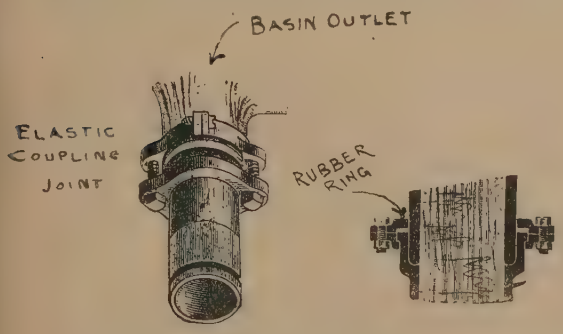
cure and reliable, forming a first-rate connection with the soil pipe branch, the plumber merely having to make a wiped joint between the two.



Figs. 61 and 62.

Jennings' elastic coupling and union joint, as illustrated (Figs. 61 and 62), ensures an air-tight connection between the soil pipe and closet

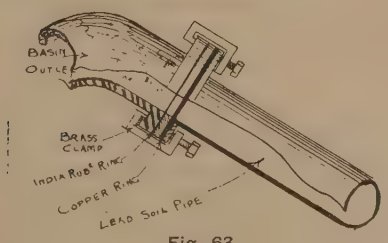


Fig. 63.

basin. Another connection on a similar principle to the latter is the clamp and rubber-ring joint Fig. 63). The brass socket and cement caulked joint (Fig. 64) is frequently used, and when properly executed renders a safe connection.

The action of frost on ordinary closets and

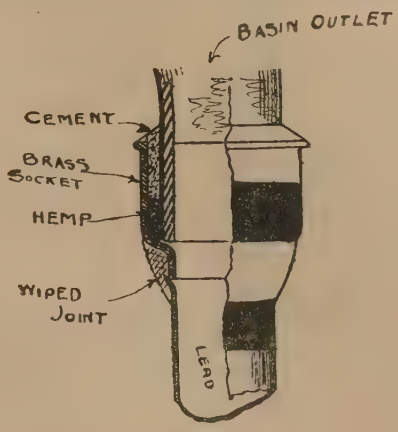

Fig. 64.

flushing apparatus when in exposed positions is sometimes very destructive and injurious to their effectual working. Special provision should therefore be made to prevent freezing, and to do this

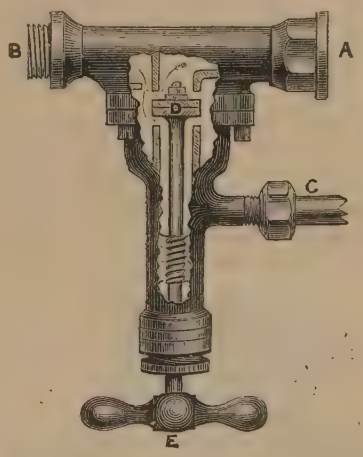

Fig. 65.

where the pedestal closet and arrangements are used, they should, together with all waste pipes, be fixed on the least exposed wall, and the water-supply pipe provided with a frost tap, such as Simpson's

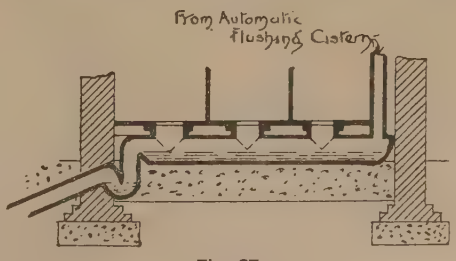

Fig. 67.

patent (Fig. 65), so that the water may be turned off and drawn from the pipes during severe frosty weather when not required for use. The closet-

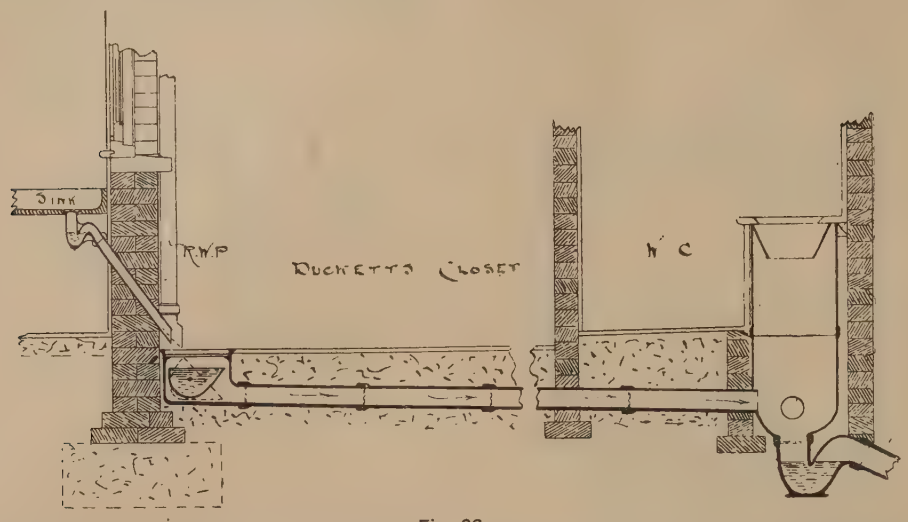

Fig. 66.

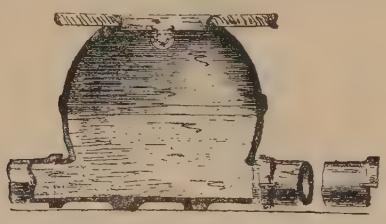
basin should also be provided with a cover which should be kept closed, and a small quantity of kitchen salt sprinkled with the water of basin will further prevent freezing.

Some excellent closet contrivances have been invented for cottages and other small properties. The slop-water closet, such as J. Duckett and Son's (Fig. 66), which is largely used, is so constructed that the soil is removed from the apparatus by the waste water from sinks, baths, and rain-water gullies, which is conveyed to a vessel or tank holding 3½ gallons. This upon becoming full tips up or syphons out and automatically flushes the apparatus and drains, the former again regaining its



JENNING'S SYPHONIC TROUGH CLOSET

Fig. 68.

upright position. These closets are not subject to defects through frost, and do not require the use of fresh water for flushing. Another apparatus specially adapted for factories, schools, and places where it may be subjected to rough usage is the trough closet. This consists of a stoneware or white porcelain enamelled iron continuous trough, provided with closet seats at intervals in separate compartments, thus forming several closets. The floor of this trough is made with a slight fall towards the outlet, where it is again raised to form a basin to contain water, beyond which is a trap similar in construction to other closets (Figs. 67 and 68). It is generally flushed by means of a tank cistern working automatically, or the foregoing tipping arrangement can be used.

THE SALARIES OF SANITARY INSPECTORS.

WHAT MR. TIDMAN THINKS.

SIR JOHN HUTTON recently stated that the number of Sanitary Inspectors under control of the Medical Officers of Health in the county of London is about 200, each having an average of 3000 houses with 25,000 persons to look after.

Mr. Hy. Tidman, hon. sec. of the Sanitary Inspectors' Society, remarked to a *Morning Leader* representative that "a thousand houses to each man would be quite as much as he could manage. That meant testing at the rate of three or four houses a day, which with his many other duties would well occupy him."

The payment of these officials ranges from £91 per annum up to a maximum of £350, the lucky recipient of which is the Chief Inspector of Bermondsey.

The Public Health Committee of the London County Council have sent a recommendation to the Council that it should ask for the assistance of the Local Government Board in an endeavour to raise the rates of payment.

"The result of the present low salaries is," said Mr. Tidman, "that we get an inferior class of men in some cases. Battersea is now advertising for a man at £91—and for that sum he has to go through a training and pass a very trying examination."

"Another thing I should like to mention," he added, "is the failure of the Metropolitan Board of Works, and later the County Council, to make bye-laws for the regulation of drains. If that were done throughout the whole of the metropolis it would, besides being of great use to the Sanitary Inspectors by making one uniform system, be of general public benefit."

Many London parishes have an excellent staff of Sanitary Inspectors, but others need bringing up to the mark.

INCORPORATED

Society of Medical Officers of Health.

METROPOLITAN BRANCH.

AN ordinary meeting of the metropolitan branch of the Incorporated Society of Medical Officers of Health was held on Friday afternoon at the offices of the St. Giles's District Board of Works, 197, High Holborn. Dr. Gwynn (Hampstead), the president of the branch, occupied the chair, and those present included Drs. F. J. Allan, S. Davies, L. A. Bryett, S. R. Lovett, J. Herron, W. A. Bond, R. Dudfield, J. F. Sykes, H. L. Bernays, and O. Field (hon. secretary).

A communication from the Council of the Incorporated Society, submitting a series of questions as to the desirability of amendments in the law relating to the notification of infectious disease, was considered.

Among the alterations suggested was that measles should be added to the list of notifiable diseases, but the penalties on convictions were regarded as inadequate.

The London Building Act, 1894, Amendment Bill was considered.

Dr. ALLAN said that he thought Medical Officers generally would agree with the principle of the Bill.

Dr. SYKES pointed out the ultimate result of legislation of this character was to make the working classes a specialised class. But such Acts as these really stood in the way of better provision of dwellings for the working classes, for the conditions were so severe as to be almost prohibitive except for pure philanthropists. He thought that very few more working-class dwellings would be erected by private enterprise, owing to the competition created by the London County Council, and the County Council could after all only touch the fringe of the question. The effect would be to create a privileged class, for they had dwellings with more light and air than other classes could afford. The whole thing was a vote-catching business carried on by both sides, and it was not a commendable process. If there was a principle applicable in such matters it ought to be applied to all alike, and not to a section of the community only.

The CHAIRMAN remarked there was nothing they could object to in the Bill as Medical Officers of Health, and it was simply a question of politics.

The Midwives Registration Bill was also considered, but as this is before the Council, it was not thought necessary to discuss it at this juncture.

No action was taken in regard to either of the measures.

In accordance with notice of motion, Dr. R. DUDFIELD moved:—"That a communication be addressed to the Metropolitan Asylums Board, with a view to securing information as to the discharge of patients from their hospitals, and as to the removal of patients in the Board's ambulance from one sanitary district to another." He said that what was desired was three sorts of information, which would not involve much trouble, and they would be exceedingly useful. The first was that the Board should notify to Medical Officers of Health the removal of patients from one district to another, and he cited cases in which there had been great detriment to the community through this having been done. He also wanted regular notices of errors in diagnosis, of course, to be sent to him in confidence, and also the dates of the discharge of patients home. In London nothing of this was known at all, and the information would prove invaluable to Medical Officers of Health.

Dr. F. J. ALLAN seconded the motion, and reminded the members that at the last meeting of the Incorporated Society Dr. Goodall, of the Metropolitan Asylums Board, had emphasised the fact that patients were discharged with cautions not to at once mix with other members of their family. At present there were no means of ascertaining whether this injunction was carried out, and, in many instances, if the Medical Officer of Health knew of the discharge of the patient, he would be able to see that this regulation was enforced, thereby preventing the occurrence of many infectious cases.

The CHAIRMAN remarked that the question of the errors in diagnosis might lead to friction.

Dr. DUDFIELD said they would always be regarded as confidential.

The CHAIRMAN said that then they could not be made use of.

Dr. DUDFIELD rejoined that the only use he wanted to put them to was to verify his statistics and help to clear up inquiries.

Dr. ALLAN said it was done in many cases.

Dr. SYKES observed that the only thing that struck him was, that while he quite agreed with Dr. Dudfield's suggestions, whether they were not asking too many things continually from the Metropolitan Asylums Board. He felt, however, that the Medical Officers of Health were not enough in touch with the hospitals and hospital work in the metropolis, and it was an unfortunate position to be in. If there was to be a radical change in the Metropolitan Asylums Board, they should endeavour as Medical Officers to get into closer touch with the administration. He did not mean, of course, in any way to interfere with the management of the hospitals, but be in closer touch, to remove some of the existing defects of the system.

The motion was carried *nem. con.*

A hearty vote of thanks to the President closed the meeting, after several business matters had been disposed of.

Sanitary Inspectors' Associations.

THE NORTH-WESTERN AND MIDLAND.

THE thirteenth annual meeting for the present session of the above Association, was held at the Liverpool Royal Institution on Saturday, the 12th inst. The President (Dr. Vacher) occupied the chair.

The successful completion of the arrangements for amalgamation with the Carnarvonshire Sanitary Inspectors' Association was announced, and twenty additional members were elected. Some further routine business having been disposed of, the Chairman called upon Mr. Ernest Worrall, Mem. San. Inst., F.R. Met. Soc., Surveyor and Inspector, Penmaenmawr, to read his paper on "Some Public Health Problems."

Mr. WORRALL at the outset referred to the fact

that the previous addresses which appeared in the Association's "Transactions" for the current session, had been mainly of a technical character, dealing with specific subjects, so that it had been thought not inappropriate to conclude the series with a more general survey of some problems which concerned them as officers in the sanitary service.

A problem in public health procedure, and a many-sided one, too—one which affected the large and small governing bodies alike—was the complexity of English public health law. Scotland had obtained codification, and was in this respect distinctly in advance of her southern neighbours. When so important and influential a personage as Lord Russell described the existing confusion "disgraceful," ordinary people would anticipate an imminent attempt at improvement. Although sanitary law was not entirely omitted from the sessional programme of Parliament, several small and needed measures being included, these measures seemed likely only to make confusion more confused. Nothing but the total repeal of the whole of the existing enactments, and the inclusion of their necessary provisions in a concise, workable, and intelligible sequence, would meet their requirements. All this had been said, and better said, by others before, and it might be asked, What was the use of repeating it? The answer was that it was only by continual demand in season and out of season that they could hope at length to arrest a sufficient public attention to the subject to ensure its being seriously taken up by the Legislature.

The machinery devised or improvised to give effect to the present sanitary law, commencing with the Local Government Board, afforded just cause for complaint. The Earl of Kimberley, at all times a sober-minded speaker, recently stigmatised the position of affairs at the Local Government Board as "amounting to a grave public scandal." They would remember a recent circular-letter addressed to Urban and Rural Sanitary Authorities consequent upon two calamitous typhoid epidemics, urging them to inquire into and report upon their water supplies, and in case of doubt to at once take steps to remove the source of danger or provide new supplies. The circular was a very proper one, and conveyed the idea that those who directed its issue were in real earnest. It was difficult to reconcile that view with a subsequent fact. An Authority, within the area represented by that Association, being desirous of improving the water supply to portions of its district, prepared a suitable scheme and submitted it, together with the formal application to the Local Government Board. The Board's local inquiry was held, after a considerable lapse of time, and there was no opposition or question as to the merits of the scheme. A reason advanced in its support and for its speedy execution was the possibility of pollution of an existing supply. This was in December of last year, and up to the time of writing that paper the sanction had not been forthcoming. As to remedial measures, some proposals aimed at ending, and some worked for mending, the institution. As the executive officers in public sanitary work they could not afford to leave the discussion of this matter entirely to others. There were those who would allocate a very lowly portion to their share in the matter, but they believed that the day had gone by that the Sanitary Inspector only interested himself in bad smells and defective drains. Individually and collectively, and especially through the medium of an Association such as theirs, they could aim at higher things, and, with the experience gained in the course of the exceptional opportunities afforded by their daily work, they might prompt, as no one else could, the conclusions of those who would be responsible for the change when it was made. To safeguard and further their interests in commerce there was the Board of Trade, and to deal with matters concerning agriculture there was the Board having that name; the Navy also had its Admiralty Board. Important and necessary as these were, they were scarcely more so than would be a Department of Public Health.

It was no fault of the Local Government Board that, as now constituted, it was unequal to the task. As regarded its health work, it chief defect was that much of its work was in the nature of curative rather than preventive effort. It was a very good thing to have long and searching inquiries into causes of epidemics as the means of compiling reliable data for future guidance, but it would be a vastly better thing to make such epidemics less possible. What was wanted was a close, if not a closer, supervision by an authoritative department, with a responsible Crown Minister at its head, of many so-called Sanitary Authorities throughout the country. There was a real need for such supervision. The reign of Bumble had not ceased, as might be read almost any day in the columns of a Press report of Urban and Rural Council procedure.

The next problem to be considered was the absence of continuity in the *personnel* of the Local Sanitary Authority. As a whole, and in principle, the electoral system of representative government was not to be despised. It was the outcome, the only possible outcome, of the democratic advance, which would pass into history as the main feature of this expiring century. But good as the system was, it had some melancholy defects, chief among which from the sanitarian's point of view was the one referred to. Its immediate effect was the doing in a spasmodic and piecemeal way work which could best be done by constant systematic application. Its ultimate effect was to slow the progress of sanitation, to minimise the health and happiness of life, and to lessen the remoteness of death. It had been said that a Corporation had nobody to kick, that responsibility for wrongful acts of omission or commission could not be allocated to or felt by the individuals composing it, and sins against the public health formed the exception to the rule. It was otherwise when some one or two persons were directly responsible for all they did or left undone. Blame or merit was better understood by everyone concerned, and, consequently, there was better effort to deserve more of the latter, and little of the former. If such were a logical conclusion, the lesson, then, surely pointed to a means to the end, namely, individual authority.

A solution, and a tried one then, for the problem under notice was to invest the executive Health Officer with much of the authority now imposed upon his Committee of the Local Authority. An Inspector or Medical Officer worthy of his calling would, in the credit and confidence thus bestowed, bestir himself all the more to make his office a still greater power for good. A remedy of the kind proposed would necessarily carry with it the re-

moval of another brake on the procedure of Health Officers; one which would hasten sanitary advance and free the responsible official from worries that, in themselves, weighed down many a conscientious and zealous disciple of hygeia.

Mr. WORRALL also referred to the question of "security of tenure in office," dwelling on its extreme importance, but pointing out that it would be worth while, in supporting this proposal, to be at some pains in dissociating the personal element as much as possible, laying stress more upon the fact that it was the public, and not the officer, that would be most benefited by freeing him from self-interested or stupid opposition. Doubtless the eventual and permanent solution would be in the education of the public up to its need, and its very direct bearing upon a subject of vital interest to it.

The PRESIDENT initiated a discussion which proved to be of a very spirited character, the following members participating therein:—Messrs. Wm. Urquhart (Crewe), W. Bland (Urmston), W. Curry (Droylsden), R. John Hughes (Rhyl), H. H. Spears (Waterloo), and W. Stansfield (Manchester).

A hearty vote of thanks at the close was accorded Mr. Worrall, and with his reply the meeting terminated.

A meeting of the Association will be held at Stafford on the 26th inst. to consider the desirability of forming a special Midland centre, the recent increases in membership having, in the opinion of the Council, fully justified that step. The proceedings in connection with this meeting promise to be of an interesting character. Members arriving at Stafford Station at 12.30 noon will be met by Mr. Wm. Blackshaw, Assoc. M. Inst. C.E., Borough Engineer, and Mr. Jno. Evans, Chief Sanitary Inspector, Stafford, who will conduct the party over the sewage works, the Royal Brine Baths and the county building. A meeting will be held in the Shire Hall at 3 p.m., when in addition to the consideration of the special business above referred to, Mr. Arthur Kent, Assoc. San. Inst., Sanitary Inspector, Hanley, will open a discussion on "The Protection of Water Supplies." Tea will be served at the Dolphin, Stafford, at the conclusion of the meeting. The attendance of Midland Inspectors generally is invited.

BONNYBRIDGE.—The ceremony of turning on a new water supply for Bonnybridge was performed on Wednesday, the 16th inst. The duty of turning on the water was given to Mr. George Ure, of Wheatlands, the pioneer of Bonnybridge iron-founding industries, and a prime mover in obtaining the water supply which has been so successfully brought about.

LYDD.—The disinfector building is not only finished, but it is now fitted up with the disinfector apparatus complete. Fires have been lighted, and the efficiency of the apparatus tested during one or two days, and it appeared to answer its purpose excellently. As soon as the cart to convey disinfected clothes from the building is obtained the disinfector will be ready for use when required. The entire cost of building, apparatus, carts, and everything will probably not exceed £200. The situation is an excellent one; it is on the East Ripe, and distant some 200 yards or more south-west of the railway station.

LOOKING AHEAD: A PEEP INTO TWENTIETH CENTURY SANITATION.

By M. INGRAM, Manchester.

IT is a truism to say that the Victorian reign has been one record of scientific success, and that few sciences have made more rapid advances than that pertaining to public health, attention to which was caused by the lamentable illness of the Prince of Wales in the year 1871. Its progress since then has been little less than a revolution, if we but compare the progress (or want of progress) of ages with the good work accomplished since that epoch-making year—a year which may be described as the pioneer of modern sanitation, and the alpha of sanitary science, the practice of which is as varied in character as in its application to the habits and conditions of the people whose life and health it is desired to safeguard.

For reasons which it is unnecessary for us to enter into here, large numbers of people assemble together in our towns and cities in far too circumscribed an area, which circumstance makes it incumbent upon us to understand why certain diseases occur or exist under a certain set of circumstances and conditions, and are wholly absent and do not exist where the social and physical conditions are changed.

Let us make a comparison between a migratory and a stationary community. The former, most likely, would be pastoral in occupation, and by reason of attention to their flocks and herds would be constantly changing their quarters as pastures became bare; their habitations would doubtless be huts or tents which could be pitched near a clear and unpolluted spring, brook, or river, either of which would supply one of the necessities of life, whilst food—a plentiful supply—would be always at hand. Clothing suitable to their wants, the skins of their flocks would supply in abundance; from the inclemency of the weather their huts or tents would afford protection; whilst the atmosphere, unpolluted by man, would supply the other conditions of health. It is safe to assume that these people would live a natural and a healthy life, and the chances of longevity would be far greater than in a congested district, where, by the exigencies of employment, we must of necessity live in an atmosphere polluted by nature's calls, and by man's indifference to man.

We readily admit that the constitution of our society makes the natural state of our present-day existence not at all on all fours with the case first cited, nor can we ever hope, by the adoption of the best and most scientific means at any time at our disposal, to obtain conditions so favourable to health and so conducive to long life; but we do claim that much more can be done than is done in this direction.

"Earth to earth" has long been voiced both by sanitarian and agriculturist; it has much to recommend it, but its application to the wastes of civilisation has hitherto been a disappointment and loss to its advocates. There is, however, no reason why it should be abandoned, for the wastes of life and the organic refuse of civilisation must be quickly disposed of; in fact it is an elementary duty of all communities. The perfection, or want of perfection, of its collection and its disposal, reflects itself in the physical, moral, and social well-being of

such community—this is well understood. Were it not so, history would be false, science a sham, and legislation both foolish and futile, and the evidences of one's senses would be in vain.

Bad sanitation demoralises its environments; it pollutes the air as well as the water, each the most important element of life. Contamination of the latter has caused some of the most baneful of epidemic diseases, whilst the pollution of the former is one of the chief causes conducive to a lowered state of health, also to drunkenness, poverty, and not unfrequently to crime, for it is said that incapacity for work, and a disinclination to work, act with the same force, so that when one is present so also is the other.

From cause to effect we trace this fact—that the industrious classes feed and clothe an army of able-bodied paupers, tramps, loafers, and criminals, who "neither toil nor spin" (except when on the tread-mill), but who engage the larger portion of the time and energies of our civil governing bodies in protecting the other portions of community from influences inimical to the general well-being of the people at large.

For reasons unnecessary to enumerate here, towns and cities in this country are built upon the banks of rivers. Advantage has hitherto always been taken of this circumstance to get rid of the wastes of life by allowing it to enter into the flowing waters, irrespective of the injury caused to those residing on a lower level. This method obtains in the largest cities as well as in the smallest hamlets in this country.

We have in our mind a small village, all the houses of which are built on the verge of a beautiful clear stream, the source of an important river, the home of the lusty trout as well as of the beautiful kingfisher. The sanitary conveniences empty direct into the flowing stream, where you may see—if you have an observant eye—not infrequently one member of a family fetching water at the *front* of the house for the morning or noon-day meal, whilst another is polluting the stream at the *back;* and for many miles this river is both the domestic water supply and the outfall for sewage. When it reaches an important city some miles still further it is then little better than crude sewage.

This state of affairs should be condemned by all intelligent men, and should be absolutely forbidden by law. Law, however, is seldom in advance of public opinion. It should therefore be the duty of all sanitarians to educate public opinion, and so hasten legislation which will effectually prevent the pollution of our rivers and their tributaries by local Sanitary Authorities, who so flagrantly violate the laws they are now commanded to obey.

The ninteenth century has been so fruitful of scientific triumphs, that we shall be sorry to think that science is so impotent, engineering so helpless, and chemistry so played out, that no practical plan can be devised to hasten a revolution in the methods of collection and disposal of the wastes of life and domestic refuse, which will not be an improvement upon the plan now in operation in this country.

"Looking a-head," say, thirty or forty years, let us assume that education, both technical and scientific (which, thanks to a wise Government policy for half-a-century past, has made the great mass of the people in this country alive to their own physical welfare), has impelled them to join together and forced the Government to solve the sewage problem, which up to this time has been in the hands of local governing bodies, without either the power or the means to perform the duty imposed upon them.

It was seen how beneficial to the community had been the collection and distribution of our letters and parcels by Government organisation; it had been a national benefit. Could any one doubt a national system of sewage would be less so?

We can look backward from this forward period, and ask with astonishment how a so-called practical people could ever tolerate legislation which in effect prevented them as a community from doing that which the law commanded them to do.

How was it possible for Manchester, for instance, to collect and dispose of the wastes of life and other domestic refuse within her own boundaries without jeopardising the health and the lives of the whole community?

It was found impossible, and so opposition from adjoining Authorities, armed with similar powers, had to be purchased or fought in the Law Courts at great cost, which costs came out of the local treasury—whereas the benefits derived from improvement in public health, even of a single district, are of national importance, and should be so considered.

And so it came to pass that a national system of sanitation was established in this country. Let us imagine how it is applied.

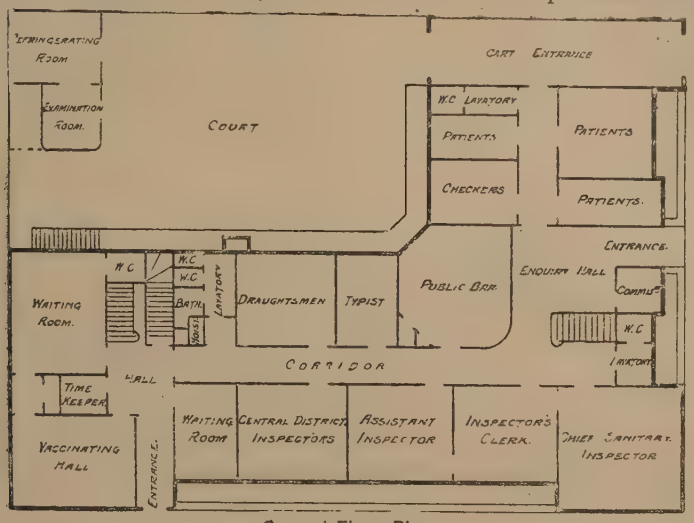
Its first and foremost principle is that every domestic dwelling in every town and city in the kingdom is to be cleared of its sewage and all other putrescible refuse at every hour of the day—in short, as soon as it is made; motive power for this purpose is provided at suitable centres of such towns or cities. There is no accumulation, therefore no stagnation, either in the house or any point of transit to such centres; all objectionable matter is removed the moment it is placed within an apparatus provided for it, both in each house and other convenient places; the matter is thus despatched to its proper centre before decomposition makes it injurious or offensive. On its arrival at its proper centre, it is still kept in brisk motion, and automatically, as it were, diverted to the direction it is desired, until it finally arrives at its ultimate destination—the land—where it gives back to the soil that which has previously been abstracted from the soil to produce it; and, enriched by such fertilising matter, who can wonder that agricultural depression is a thing of the past, and that our farmers, having abundant manure at hand, can and do compete with success with the foreigners in our home market, with profit to themselves and a benefit to the community at large?

In considering the question of nationalisation of sewage removal and disposal, it was seen that the whole kingdom was practically planned out, ready surveyed and levelled by the existing railways and the admirable public roads and highways which intersect and traverse every town, village, and hamlet in the kingdom. It was therefore decided that railways also should be nationalised, much to the advantage of the whole community.

(*To be continued.*)

GLASGOW NEW SANITARY CHAMBERS.

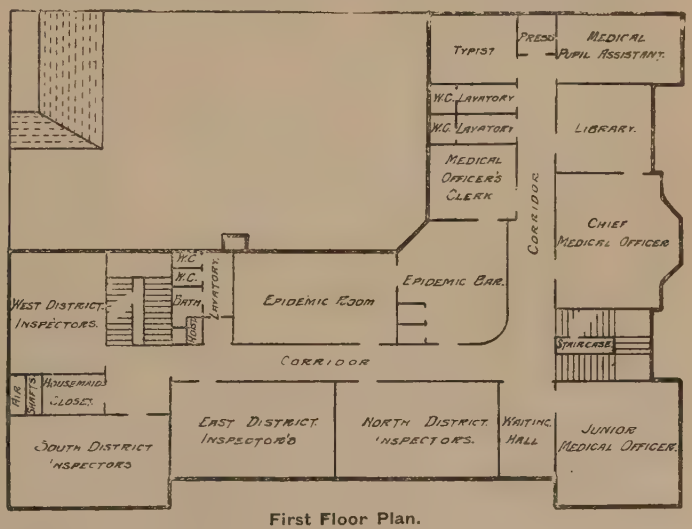
A BRIEF description of the new chambers which the Sanitary Staff have lately entered will be of interest to our readers. The foundation stone was laid on 25th June, 1895, and the staff removed to the new premises on 3rd May last. In THE SANITARY RECORD, May 1st, 1896, we gave a view of the elevation to Montrose-street. We have now the pleasure to submit ground plan details of three of the flats. The Sanitary Department of Glasgow, as at present constituted, dates from the year 1870, when the first Sanitary Inspector, Mr. Kenneth M. Macleod, with a staff of forty-five all told, was appointed. Year by year the staff has gone on increasing, until now it numbers 172, necessitating enlarged premises.



Ground Floor Plan.

A part of the basement of the building is devoted to store-rooms for the old books, documents, &c., one room worthy of mention being a fire-proof one where all the returns made by the Registrars to the Medical Officer during past years are arranged on iron shelves. These returns comprise births, deaths, and vaccination defaulters. The volumes are all bound in half-calf, and labelled in gilt letters so that they may be of easy access. Other store-rooms are devoted to oils, waste, sulphur, turpentine, and other material used in the smoke testing of drains. There are at present ten lads specially set apart for the testing of drains, under the supervision and directions of the assistant Inspectors. Each tester has a press or locker with a key, in which is deposited the smoke-testing machines, india-rubber tubing, and other appliances in connection with drain testing. A set of engineering and tinsmiths' tools are provided in the smoke-testers' room, so that any necessary repairs may be performed on the premises instead of having to employ, as formerly, outside tradesmen. Another apartment is set aside for the lime-washers of infected apartments. There are at present four of these men, who have been previously painters by trade. The quantities of whiting, colours, and disinfectants are supplied to them every morning by the man in charge of the premises. Each man carries a satchel, brush, and pole in his rounds, but at present the Health Committee have under consideration a method of adopting a motor car for disinfecting purposes. It may be stated that previous to the whitewashing process, the men who collect the infected clothing from the disinfecting station at Ruchill or Belvidere, as the case may be, carry out the fumigation of the apartments by roll sulphur mixed with a small quantity of chlorate of potash.

In the basement is situated the boiler and furnaces for heating the offices on the low-pressure steam system. The pipes are carried throughout the building, and each apartment has regulating valves. In the lobbies are several American radiators. Some of the apartments, a shown on plan, have fire-places. The ventilation is on the extracting principle. In the specially-constructed spaces in the bossings of the windows the fresh air passes from an external grating in the wall over radiators and is heated. The top of the casement has a perforated wire gauze and grating. The fresh air can be regulated by a shut-off valve with brass handle as may be deemed necessary. The exhaust atmosphere is drawn off by louvre gratings placed one about 3ft. from the floor in side wall, and one at the top of side wall next to ceiling. These louvres are regulated by a cord betwixt them. That is to say, one of them always remains open whilst the other is shut. Ducts run underneath each floor to a specially-fitted apartment on roof provided with



First Floor Plan.

two Blackman fans driven by electric motors. The building is lighted and the motors driven by electricity from the Corporation mains.

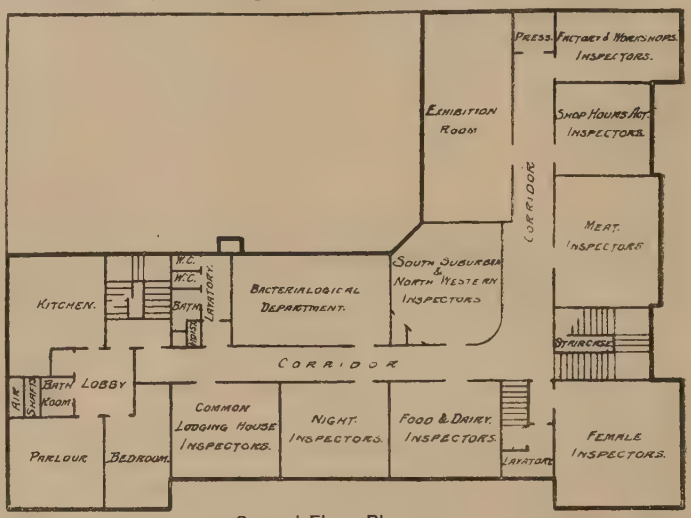
Each flat is provided with two wash-out closets, a set of three marble wash-hand basins with hot and cold water taps, and a bath for use of the employés. As will be seen from the plan, there are also other conveniences and lavatories for use in connection with the special apartments adjacent thereto.

The public entrance is by Montrose-street, and the entrance for the staff by Cochrane-street. Entering by the former, there is a spacious vestibule, the floors and walls of which have ornamental and coloured encaustic tiles. The public inquiry bar is at the end of this vestibule, provided with a sliding window. To the left is the Chief Sanitary Inspector's room, and in communication therewith the rooms for his clerk and Assistant Inspector. Keeping to the left, along the corridor is the room for the Central District Inspector and his assistants. On the right hand are the rooms for typewriter and draughtsman. Further along, at the Cochrane-street entrance, are three apartments devoted to vaccination purposes. One stair up are the rooms for the following District Inspectors and assistants, viz.:—Northern, Southern, Eastern, and Western, also room for Inspectors whose duty it is to look after infectious disease, which is an adjunct, and has access to "Epidemic" or infectious disease inquiry bar. Entering off this bar is the Medical Officers' clerk's room, and further in the passage is the room for Medical Officers' typewriter. The veterinary surgeon (a recent appointment) has an apartment adjoining that of the senior Medical Officer. The senior and the junior Medical Officers' rooms are near top of staircase. They and the Chief Sanitary Inspector's room are furnished with Stanley telephone instruments connected to every apartment in the building, so that they can converse with any of the staff from their writing tables.

On the top flat are the apartments for the following Inspectors:—Workshop, shop hours, butcher meat, Food and Drugs Act and dairy, night, port, and lodging-house. There are also two rooms at present being fitted up for bacteriological research, and a large apartment in which will be exhibited improved sanitary appliances.

The desks, writing tables, cabinets, presses, and indeed all the furniture is of Austrian oak, with the exception of the Medical Officers' library, which has an apartment to itself, and is of walnut. Great pains were taken by the city architect, Mr. A. B. Macdonald, and his assistants to have everything carried out in a substantial manner.

It should be mentioned that in the courtyard is a special building for the storage of unsound butcher meat when waiting the decision of magistrates. It is fitted with an ice chamber, hoist, &c. Entrance to this courtyard is obtained by Montrose-street, and this entrance is utilised for the removal of stray patients who are suffering from infectious disease, and have presented themselves at the office.



Second Floor Plan.

Institute of Sanitary Engineers.

SANITARY ADMINISTRATION OF BELFAST.

(*Continued from page* 289.)

Stables.—For the regulation of these there appear to be no published rules, though there is no doubt some understanding as to their supervision by the department. The City Surveyor has some rules for the building of new ones, at least to the extent that they may not be in contact with any part of a dwelling-house, and that they must be properly drained into a suitable tank, which must not be connected with the public sewers, but must be cleaned out periodically. I fear the condition of many of the stables and their yards in the town leaves much to be desired. It is not easy to say why there should not be a set of bye-laws to which, after a limited term of a few months' notice, *all* stables should conform. An impervious floor of square setts or paving bricks laid in cement, or else of concrete, should be a *sine quâ non.* Pebble paving should be abolished for all yards, and square setts substituted, or else the pebbles well grouted up nearly level with cement—a treatment both safe and extremely durable. There should be a minimum space, say, equal to 15ft. by 5ft. by 8ft. high, for each horse, which would give a cubic space of 600ft. The manure also should be removed from every place at least once a week. In all regulations such as the above it is seldom with the large establishments that difficulties arise. Such places are easily inspected, and their owners have both the means and the intelligence to enable them to respect the law. I have reason to suspect that amongst the petty owners of horses, and other animals as well, there is a great deal of evasion of even the rudimentary laws that at present exist.

Many a small tradesman who finds a horse, and in the case of still smaller ones, an ass, a necessity in his daily business, has the animal hidden away surreptitiously in very unsuitable places. It is by accident only, or espionage, that such breaches of the law can be detected. It has frequently seemed to me that, without any additional expense to the community, that intelligent body, the police, might

be utilised for this purpose. It is their duty at present to take cognisance of defaulters against the law, but possibly from the comparative novelty of sanitary law, they have hitherto regarded themselves as outside its pale. They are, at least officially, and generally also, in fact, in total ignorance of its defiance under their very noses, although they, like their fellow citizens, suffer from its neglect. No one would desire or expect that every policeman should be a sanitary expert, or have the training requisite for a Sanitary Inspector, but they might, without much difficulty be instructed in a list of a few simple things, as to which they need not, it may be, act themselves, but merely report, so as to put the regular Inspectors upon the track of investigation and, if necessary, action as might be found desirable.

The policeman on his beat has many opportunities for observation not open to the Inspector, and is moreover on the spot by night as well as by day, and there are many things on which a pair of eyes that need not be those of an expert would be of use. Such evasions as I have noted above are some of them. Another is the disposition of objectionable soil. The Inspector perhaps only hears or sees some days after an offence has been committed, and can then perhaps only obtain insufficient evidence to prosecute upon. The evil has been done, and can only be rectified with great difficulty, or not at all. The policeman would be always within sight. Another default, which especially in a wet climate is always unpleasant to the passer-by, and when it goes so far as to render the houses damp becomes in the sanitary sense a "nuisance," is the leaky state of so many eave-spouts and down-pipes. In fine weather such things are easily missed or forgotten, but the policeman who is on his beat in all weathers has many an opportunity for taking notes.

The administration of these bye-laws that we have discussed above does not by any means include the whole, or even the greater part of the work of the Public Health Department. The Acts upon which these bye-laws have been chiefly framed are special and particular, inasmuch as they apply in the main to certain classes only of the community, but the Public Health Act itself is in its operation universal, and may be supposed to embrace within its scope all those classes who are not affected by the former. From this general nature of its application it is clear that it cannot go so much into particulars as some of the former Acts, but must leave a great deal to the individual opinion and discretion of those who administer it. For the protection of the public, on the other hand, it gives more latitude of interpretation and decision to the magistrates and others of the Judiciary, with whom rests the power of enforcing the law. In other words, the infringement of a specific clause, for instance, as to size or material is a very simple matter of evidence, and can easily be proved either yes or no; but the question whether a certain house is, or is not, fit for human habitation depends frequently upon a number of conditions and of collateral circumstances, and admits quite legitimately often of evidence very conflicting in its character.

In the smaller and worse class of houses inspection is as frequent and regular as the strength of the inspecting staff will permit. The better class houses practically receive no regular inspection, except upon some specific complaint. Such, however, are promptly attended to, and freely investigated by the Department, including where needful the testing of the drains. Where defects are discovered the owner is ordered to have them remedied, and I suppose the aid of the law would be invoked in the case of persistent non-compliance. As typical of the class of work that goes on, I may give the report for one month early in last year, which happens to be the one nearest to hand. During that time orders were made for twenty yards to be tiled, thirty gulley traps to be inserted, eighty-three privies and ashpits to be repaired. Action was also taken with regard to the water-closet accommodation in certain factories. In addition an insanitary court was with the consent of the owners closed. As an instance of the manner in which private interests are safe-guarded under the Public Health Act, and the difficulties which stand in the way of rapid action on the part of Sanitary Authorities, I may give a case in which I was to a certain degree interested.

Some three years ago a narrow court containing ten houses (of two rooms, one below and one above, in each) came under the notice of the department, and a summons was issued and the case brought before the magistrates. The yards were most of them extremely small, the combined privy ashpits abutted against the house wall, and the only means for removal of the contents was through the houses, which were generally in a dilapidated state. After much evidence, medical and other, upon both sides, it was arranged that if the ashpits were separated from the houses and some other repairs made they might still be occupied. Recently they again came under public notice, and this time an application was made definitely to the Court for their closing. After hearing the evidence *pro and contra*, and the magistrates taking the unusual step of visiting the court, an order was made for the closing. Curiously enough, there has been no case of infectious or, I believe, zymotic disease in the court for many years, the mortality being due to the poverty or intemperate habits of the inmates, attracted to the place by the extreme lowness of the rents. I have quoted this case at some length, because in the first place it shows some of the difficulties in the way of summary action on the part of the department, and one which they have themselves quoted in reply to inquiries as to why they have not been able to do more in the way of improvement.

It took three years to close a court which admittedly had many undesirable features. The magistrates had first to be convinced of the necessity, and after one decision and the improvements consequent thereon, it is evident that further legal proceedings could not be originated with any fair chance of success until after some reasonable lapse of time. It opens up, in the second place, a question of some importance as to what really constitutes a house unfit for habitation, and upon what lines the Sanitary Authority should act in such cases. In general they seem to rely upon a cumulation of bad features to establish their case, and not unnaturally perhaps it is not always those that are actually the worst which receive the greatest pre-eminence, but rather those most calculated to influence the bench. For instance, a limited yard space cannot by itself, however undesirable, be honestly declared to make a house uninhabitable,

although the proximity, and still more the actual contact of a foul refuse pit may. Again, the state of the yard is of much greater importance than its size. A perfectly impervious bottom is of far more sanitary value than a few square feet of space, and a pit covered from the rain and containing little else than dry ashes, 2ft. or even less from a house, is less objectionable than a larger one open to the wet, and with other more undesirable contents, although at three times the distance. Were absolutely impervious ashpits dry because covered, impervious pavements to yards, and the substitution of water-closets for privies, insisted upon in the case of every house, the size of yard question might be left to solve itself, and a closing order need hardly ever be applied for, because all houses which it would not pay to, or which were incapable of being so converted, would close themselves.

It must always be borne in mind that the exigencies of labour, and the extension of business premises in the centre of every large town, render it increasingly difficult for a large class of labourers to find a residence near their work, and the competition for small houses anywhere near the centre of the town renders perhaps landlords more indifferent to their tenants' welfare than they otherwise would be.

A Public Health Department is therefore doing no more than its duty when it imposes rigorous conditions of sanitation in such cases, it is not acting judiciously when it makes these conditions of such a nature as to drive this class of houses out of the field altogether.

The subjects we have discussed hitherto may be considered as among the commonplaces of sanitary administration, and represent for the most part the every-day routine of the department, but there are many branches of its work of equal, and some of them even of greater, importance. Foremost among these, and one which sometimes tries the powers of the officials to the utmost, is the dealing with infectious disease. Upon this question the Corporation of Belfast must certainly be admitted to have been somewhat backward, although it would certainly not be fair to include the officials in this charge. They have been year after year now for a considerable time urging upon the Corporation the importance of the adoption of the Infectious Diseases Notification Act, but it was only at the beginning of last year that they succeeded in persuading them to do so. Perhaps the pressure of the officials might have been stronger but for the fact that the Corporation had no infectious hospital, the only one in the city being attached to the workhouse, and under the management of the Board of Guardians. Under these circumstances, and until the Medical Officer of Health could succeed in convincing the Council of the necessity for such a hospital, he may naturally have felt that the notification would be robbed of half its value. The Corporation has now resolved upon the hospital, and fixed upon a site, and it is to be regretted that legal, or at least technical difficulties, which it may be hoped will soon be overcome, should have prevented its commencement. But the adoption of notification, and the possession of the finest possible hospital, really means only the commencement of the work, the critical question is to get all this machinery made use of by the class for whom it is intended.

And here many difficulties confront us. In proportion generally to the needs of the poor is their ignorance. Their prejudice against hospitals has been met with in many places, and certainly is no less in Belfast than elsewhere. In the matter of infectious disease also their ignorance renders them much less alive to the necessities of isolation than a better educated class would be, although in certain cases and certain diseases, especially of an unusual type, the same ignorance may manifest itself in an unreasoning panic against infection. When the proposed site was fixed upon, a spot about three miles from the town, the Medical Officer of Health obtained from a number of places replies as to whether any inconvenience was found from having the hospital at such a distance, and in nearly every case the answer was that none was felt. It seems nevertheless only natural that the poor should feel rather more reluctance to allow their relatives to be removed to a distance, practically out of reach of their friends, than they would to a place in or nearer to the town.

This raises the interesting and important question as to the adoption of compulsion, and if so whether it is to be, or could be, carried out upon all classes alike, and, if not, where to draw the line, certain as it would be to mark an invidious distinction between rich and poor. I am not sufficiently acquainted with the practice of other places to say, but it seems a great responsibility, and rather an arbitrary power, to be left in the hands of a single Medical Officer, though any other procedure might involve a serious and sometimes dangerous delay. There is the further question of the isolation of the other members of a family, among whom there may be risk of infection, which would often involve the temporary idleness of the bread-winner. I do not know how far it may be legal, but it would be quite in harmony with the spirit of the law as regards contagious disease and the slaughter of animals, to offer some definite but moderate compensation for such compulsory isolation, and the community would certainly in the long run be gainers by so doing.

In the matter of disinfection the operations of the department appear to be wisely and skilfully applied. In connection with the fever hospital at the workhouse is an excellent disinfecting apparatus of the Washington Lyon of superheated steam, worked in connection with the hospital laundry, and by a subvention made annually the Corporation have the use of this, and arrange for the disinfection of bedding, textile, and similar fabrics from any part of the town. In this apparatus, as you know, the disinfecting chamber opens upon one end into the receiving-room, and upon the other into the despatch-room, there being no connection between the two except through the chamber, into which the superheated steam is introduced several times and withdrawn, thus creating through the fibres and interstices of the fabrics a vacuum, which the steam upon the next admission necessarily penetrates. Under this process, however closely the disease germs may lurk, they are certain to be destroyed. Disinfection of houses is effected with carbolic vapour, by means of an apparatus patented by Mr. Conway Scott, C.E., the chief executive officer. His experience now for many years has been that carbolic vapour thoroughly applied is the best and surest method of house disinfection.

(To be continued.)

General News.

NOTICE.—On and after 31st March next the Annual Subscription to this Journal will be raised to 12s. 6d. to all NEW Subscribers. NO ADVANCE will be made to our friends whose names are entered on our Subcription list prior to that date, so long as they continue to Subscribe.

BOOTLE.—A water scheme is required for Kirksanton Green.

ANNAN.—The erection of a public slaughterhouse is still under the consideration of the Town Council.

SUTTON-IN-ASHFIELD. — The Urban District Council is applying for permission to obtain a loan to construct public baths.

NEWTON ABBOTT.—The Local Government Board has sanctioned the expenditure of £800 in providing a water supply for Bishopsteignton.

CHARMOUTH.—The approval of the Local Government Board is to be obtained to a loan for carrying out the proposed additional water supply for Charmouth.

FAIRFIELD.—The Urban District Council has decided to apply at once for a loan of £2000 for the waterworks purposes, and to start the work immediately.

CRAY. — The Swansea County Council has accepted the tender of Messrs. John Peterson and Sons, Glasgow, at £255,747 odd, for the new Cray waterworks scheme.

CREWE.—Measles have become so prevalent at Crewe that it has been found necessary to close four of the schools. There are between 500 and 600 cases, and deaths are being reported every day.

LOWESTOFT.—A Local Government Board inquiry has been held respecting an application by the Town Council for powers to borrow a sum amounting to £1400 for the purposes of extending the existing building used as a Sanatorium.

NORTHWICH.—It was reported to the Urban Council at its last meeting that at present there is no necessity to close any more of the elementary schools on account of the measles. Upwards of 200 cases have occurred, but it is believed that the epidemic is now on the wane.

CARNARVONSHIRE.—The influenza epidemic is working serious ravages in Carnarvonshire. About a thousand men engaged at the Penrhyn slate quarries at Bethesda are down with it, and almost the like state of things prevails in the Llanberis district. At Bangor there is hardly a house free from it.

EDINBURGH.—It has been reported to the Public Health Committee that during February there had been thirty-four seizures of unsound meat in Edinburgh, none of them, however, being of meat exposed for sale in shops. The total amount of meat seized was 10,678 lb. Six cows—three in city byres, and three brought in from the country—were condemned for tuberculosis. Under the new Public Health Act, one live cow had been seized at an auction mart in town.

ALVASTON.—The Alvaston and Boulton District Council has agreed that steps should be taken to secure a site for the erection of an isolation hospital.

WATERFORD.—At a recent Town Council meeting the proposed erection of a public abattoir was discussed. A strong opposition by city victuallers caused prolonged discussion on the subject, which was ultimately postponed.

STROUD.—The Local Government Board has sanctioned the borrowing of £4500 for the erection of public offices, and £150 for land in connection therewith, and also the borrowing of £600 for the purchase of and repairs to the baths.

DUNGARVAN.—Dr. Brown, Medical Inspector of the Local Government Board, has held an inquiry into the proposed scheme for a water supply to Ballyduff and into the area of charge. The total cost of the contemplated scheme is £1500.

WORKSOP.—At the last meeting of the Urban District Council, the Surveyor, Mr. T. Kidd, presented an estimate for the requirements for the establishment of a health department, amounting to £1560, and it was decided to obtain a loan for that sum.

BANBURY.—The Town Council, acting upon the advice of the Chairman of the Streets Committee and the Borough Surveyor, has placed an order with Messrs. Aveling and Porter for one of Morrison's patent scarifiers to be attached to its 10-ton steam roller.

HEAVITREE.—A largely-attended meeting of ratepayers was held last week, convened by a circular inviting them to offer an "indignant protest against the shameful and unnecessary waste of the ratepayers' money" by the proposed erection of an isolation hospital, at a cost of £2500, by the Urban Council.

DRIFFIELD —The annual report of Dr. Wood on the health of Driffield states that during the past twelve months 155 births and 102 deaths were registered, the birth-rate being equal to 27·1 per 1000, and the death-rate 17·8, which compares quite favourably with the rate throughout the country for urban districts.

NEWCASTLE.—At a special meeting of the Tyne Port Sanitary Authority held recently a report from the Hospital Committee was discussed at length with reference to the Authority's hulk Alliance, which was practically worn out and unfit for further use. The hulk had been inspected and found unfit to bear the weight put upon it, whilst the superstructure was unfit for habitation, and had been removed. The Committee had inspected the arrangements of the Tees Board at Middlesbrough, and now recommended that the hulk be replaced by a pontoon 160ft. by 40ft. by 7ft. deep, carrying the necessary erections for the administrative block in connection with the Floating Hospital, including offices, caretakers' rooms, nurses' quarters, &c. It was also proposed to remove the Floating Hospital further south, and to place the pontoon next to the river, with a connection with the hospital. Mr. Black (of Sir W. G. Armstrong, Whitworth, and Co.) had prepared plans and estimates of a pontoon in steel which amounted to £3190. It was finally agreed to forward the plans to the Local Government Board, with a request for permission to borrow £3500; and also for an early inquiry, as the matter was urgent.

Personal.

MR. H. HILLIAM has been appointed Inspector of Nuisances for the rural district of Kelton.

MR. H. HILLIAM has been appointed Inspector of Nuisances for the rural district of Easton.

MR. J. R. BAGSHAW has been appointed Sanitary Inspector for the Lewisham sanitary district.

MR. T. C. LAWSON has been appointed Medical Officer for the fourth district of Devizes union.

MR. W. P. JONES has been appointed Inspector of Nuisances for the urban district of Glyncorwg.

DR. JAMES SHIMELD has been reappointed Medical Officer of Health for the urban district of Ilford.

MR. LLEWELLYN JONES has been appointed Inspector of Nuisances for the urban district of Holywell.

MR. WM. TRIPP has been appointed Inspector of Nuisances for the urban district of Bishop Stortford.

MR. M. C. WARNE has been appointed Inspector of Nuisances for the rural district of Maldon.

MR. F. POOL has been appointed Inspector of Nuisances for the urban district of South Bank-in-Normanby.

THE salary of Mr. Wilson, C.E., Surveyor for the rural district of Cockermouth, has been increased by £50 per annum.

THE salary of Dr. Annis, as Medical Officer of Health for Huddersfield, has been increased from £400 to £500 per annum.

MR. HARRY MASON APPS, F.I.S.E., A.S.I., has been appointed Sanitary Inspector to the Hollingbourne (Kent) District Council.

MR. WARD has been appointed Borough Surveyor for Derby, at a commencing salary of £600 per annum, increasing by £50 a year to £750.

MR. BENNETT has been elected Sanitary Inspector for the rural district of Hinckley, at a salary of £50 per annum, and Surveyor, at £50, for twelve months.

MR. SAMUEL BROADHEAD, of Stockport, has been appointed Surveyor and Sanitary Inspector under the Milford Haven District Council, in place of the late Mr. W. Summers.

MR. WILLIAM WATSON, Assistant Surveyor, Arbroath, has been appointed Burgh Surveyor, Water Manager, Sanitary Inspector, &c., for the Burgh of Maybole, at a salary of £120 per annum.

MR. S. E. BURGESS, A.M.I.C.E., Surveyor to the Stoke Newington Vestry Council, London, N., has been appointed Borough Engineer and Surveyor to the County Borough of South Shields, at a salary commencing at £500, rising by annual increments of £25 to a maximum of £700.

MR. GAYTHORNE YOUNG, of Romford, Essex, has been selected for the position of Analytical Chemist at the Great Northern Plant Works in Denaby, in the place of Mr. J. W. Young, who, has resigned the appointment in order to take up a more lucrativepost at Newcastle-on-Tyne.

Sewerage Schemes.

[TO MUNICIPAL ENGINEERS AND SURVEYORS.—The Editor will be pleased to receive items for publication relating to sewerage schemes projected or inaugurated, together with explanatory diagrams or photographs. The former should be drawn and lettered in black ink.]

THE Helston Rural District Council is applying for permission to borrow £500 for carrying out sewerage works.

THE expenditure of £1000 is necessary at the Walsall sewage farm for the re-laying of drains which have gradually become choked.

A LOCAL Government Board inquiry has been held at Sherborne to inquire into the reports upon a sewerage scheme, for which borrowing powers to the extent of £8000 were asked.

THE Rural District Council of Lanchester has instructed its surveyor, Mr. J. R. Lupton, to prepare plans, sections, and an estimate for the sewering of Cornsay village, Co. Durham.

THE Huddersfield Town Council has instructed the Borough Surveyor to prepare a report specifying the manufactories discharging trade effluents into the sewers, the nature of the effluents, and the mode and channel by which they are discharged.

A SCHEME of sewers and sewage disposal by precipitation and filtration for Roade, Northampton, prepared by Walter Shaw, engineer, The Drapery, Northampton, has been sanctioned by the Local Government Board. The work will be constructed on the "Cosham" system.

THE Urban District Council of Otley (Yorks) has received a letter from the Local Government Board in connection with the application for sanction to borrow £4000 for the improvement of the sewage disposal works, stating that as the scheme as proposed would not provide for the effectual purification of sewage at the outfall, the Board was not prepared to sanction any loan for the scheme.

A LOCAL Government Board inquiry has been held at Norwich into the application of the Town Council for sanction to borrow £12,500 for working of sewerage. It was explained that the Corporation were the owners of a large sewage farm at Whitlingham, two miles outside the boundary of the city, on the south-east side, 503 acres in extent, laid out for broad irrigation. The effluent was almost entirely absorbed by the land, and scarcely any found its way into the river Yare. The Corporation were re-sewering their city, and by their local Act of 1889 they had borrowed £80,000. Since then they had borrowed £72,000. The rapid increase in the outlying parts of the city necessitated an extension of the system, and it was on account of this extension that the present loan was asked for.

THE Local Government Board has written the Newton Abbott Rural District Council refusing to sanction the application for leave to borrow £600 for works of sewerage and sewage disposal at Ipplepen, and stating that in the opinion of the Board the scheme is incomplete and unsatisfactory. As, however, the parish is clearly in urgent need of a proper system of sewerage and sewage disposal, the Board suggested that the District Council should consult a competent engineer with a view to the preparation and submission to the Board of a satisfactory scheme.

THE Rivers Committee of the Manchester Corporation, at a meeting in the Town Hall last week, had under consideration the proposed biological scheme of treating sewers which was recommended for adoption by the effluent sub-committee, who has had the matter under consideration. The cost of the new scheme is estimated by some members at as little as £60,000, but this amount is largely exceeded in the estimates of the City Surveyor (Mr. De Courcy Meade), who has been instructed to prepare plans of the new bacteria beds proposed to be erected at Davyhulme. The Committee resolved to begin experiments with the system on an area of four acres only. If the tests to which the scheme will then be submitted prove satisfactory to the Committee and the Mersey and Irwell Joint Committee, it is considered likely that it will be finally adopted. The Committee also decided to ask the Mersey and Irwell Joint Committe to sanction an extension of time for carrying out the necessary works.

A LOCAL Government Board inquiry was held on Tuesday, the 15th inst., into the application by the Sherborne Urban District Council for sanction to borrow £8000 for works of sewerage and sewage disposal. Mr. Thomas Farrell, the Council's Engineer, gave evidence as to the new outfall and other sewers to be constructed, and stated that the purification works are designed on the latest and most improved system. The sewage on leaving the 2ft. outfall sewer passes into screening and detritus chambers, then to mixing chambers, and thence into two Candy circular precipitation tanks, 23ft. in diameter by 13ft. deep, fitted with automatic sludge removal apparatus, and finally on to the oxidising and aërated polarite filter beds. The two precipitation tanks have a capacity of 40,000 gallons each, and are capable of efficiently treating upwards of 400,000 gallons per day, and the four polarite filters, each of 136 square yards, will effectually purify 500,000 gallons per day. On account of the small tank and filter bed area required for the "International" process the system is the most economical, it being much cheaper than those methods which involve the use of very large areas of tanks and filters. The International Company's constantly aërated polarite beds may be described as the highest form of biological filter, effecting rapid purification by oxidising the organic matter, the results obtained by the oxidation and aëration system of filtration (originated and successfully carried on by the International Company for many years) being now generally attributed to the action of bacteria.

THE Local Government Board has sanctioned the borrowing by the Rural Council of Chadwell St. Mary, of £250, for the purpose of extending the sewer in the Church-road. This work of extension has been greatly needed for a long time past.

THE Brightlingsea District Council has decided to adopt a sewerage system, and to apply to the Local Government Board for £9000 to carry it out. Originally the Council proposed a scheme estimated to cost £6000, and the proposed outfall was into a fleet which debouched into Brightlingsea Creek, very close to a number of oyster beds. The oyster merchants raised opposition, and the Local Government Board, when approached, suggested an extension whereby the outfall should be into the lower reach of the Colne, about a mile away from the mouth of Brightlingsea Creek, and over two miles from any other spot where oysters were laid down for the market. The Local Government Board insisted absolutely, at the same time, upon other particulars with reference to the discharge of the effluent, and on the necessity of an entirely separate storm-water system being provided. The Clerk and Engineer to the Brightlingsea Council had an interview with the officials of the Local Government Board, and subsequently plans were prepared estimated to cost £9000. These plans included treatment of the sewage by what is known as Ive's system, and discharge into the Colne under the conditions indicated.

Lighting.

TORQUAY was lighted with electricity for the first time on Thursday evening, the 17th inst.

CONSIDERABLE alterations are to be made at Kilwinning Gasworks, including new retorts and chimney, and plans for the same have been passed by the Commissioners.

AT a recent private meeting of the Wednesbury Town Council it was decided by a large majority to oppose the application of the Midland Electric Corporation to the Board of Trade to supply the district with electricity.

THE Stirling Police Commissioners have asked Mr. R. F. Yorke, electrical engineer, Stirling, who has successfully introduced the electric light to Fort William, to give them a report on the water power available at their reservoirs for the electric lighting of the town.

THE Darvel Burgh Commissioners have been in negotiation with the Gas Light Company for some time trying to arrange terms for the purchase of the works by the burgh. This was agreed upon at an adjourned special meeting of the Gas Light Company held on the 17th inst., the terms of the purchase scheme being 25s. per share, to be paid over on June 1st next.

MR. MUNRO, in his report to the Gourock Burgh Commission, estimates that the cost of laying an installation of electric light in Gourock will be about £8600. This includes plant, sufficient to light the whole of the burgh, and the erection of sixteen arc lamps along Shore and Kempock-streets.

THE Electricity Committee of the Glasgow Corporation has accepted the tender of Messrs. Babcock and Wilcox, Limited, to provide and erect at the new electricity generating station, Port Dundas, two of their patent boilers of about 1000-horse power each, with relative superheaters, at the price of £2020.

AT a recent meeting of the Watching and Lighting Committee of the Aberdeen Town Council, a communication was submitted from the City Electrical Engineer regarding the proposal to extend the electric light in George-street as far as Hutcheon-street. The Engineer reported tha the Gas and Electric Light Committee had not yet decided to extend the mains in George-street, and in these circumstances the Committee decided to drop the matter meantime.

THE fate of the Hackney Electric Lighting Order is still undecided, and there does not seem to be any immediate prospect of the Vestry taking a decided step. The proposals of the Joint Committee for handing over the electric lighting and dust destruction to one of the three firms who have tendered to carry out the scheme were discussed by the Vestry on Wednesday, the 16th inst. After two hours' heated discussion the Vestry seems to have got no nearer to a settlement, and by a very close vote the question was again adjourned for a fortnight.

THE deputation of the Bradford Corporation which is now visiting the Continent for the purpose of picking up ideas on the subject of electric lighting and motive power has met with an unusual misfortune. Mr. A. H. Gibbings, the Electrical Engineer, who has accompanied the Mayor and Messrs. Shaw and Dixon on this tour, has been seized with illness in Brussels, and is confined to his bed. His companions have taken every possible measure to secure his speedy recovery, but at the best some days must elapse before Mr. Gibbings can get about again, and in the meantime all further movements of the deputation are suspended.

THE Electric Lighting Sub-Committee recommended to the Leamington Town Council at a recent meeting, that in view of the favourable report made by Mr. Robert Hammond, the electrical expert, the supply of electricity in the borough be undertaken by the Corporation. The Sub-Committee further recommended that the Corporation should not oppose the insertion of a clause in its Provisional Order that it should take over that portion of the undertaking of the Midland Electric Light and Power Company, Limited, which would be of use to the Corporation for the purpose of its undertaking. The Committee's report was adopted.

THE decision of the Ilford District Council to give the incandescent gas system a trial will be very welcome to all inhabitants, and it is to be hoped that the system will be found not only to be a success from the lighting point of view, but also economical to the ratepayers. So far the few lamps placed about the town as an example seem to most amply justify an extension of the system.

A SELECT Committee of the House of Lords sat on Thursday, the 17th inst., to consider the competing Bills of the Morley Corporation and the Morley Gas Company, under which the former seek to acquire the gasworks, while the gas company resist the proposals and ask for extended powers. Mr. Charles Scarth Mayor of Morley, stated that he believed the passage of the Bill of the Corporation would be an advantage to the ratepayers. He considered it expedient that the supply of gas should be in the hands of the Local Authority in the same way as the water supply was. The feeling of the town was almost unanimous in support of that view.

Correspondence.

We do not in any way hold ourselves responsible for opinions expressed by our correspondents.

RELATIVE COST OF WORKS OF SEWAGE DISPOSAL.

(*To the Editor of* THE SANITARY RECORD.)

SIR,—In our letter to the SANITARY RECORD of the 18th ult. we had no intention to disparage the excellent work which is being done at Sutton, and certainly no wish to wound the susceptibilities of anyone connected therewith. We are therefore not a little surprised at the tone of the opening remarks of Mr. C. Chambers Smith's letter in last Friday's SANITARY RECORD. We are told in that letter that "the Sutton process is not a proprietary one," but "may be copied by any other Council without payment of royalties to any patentees;" yet for merely framing an estimate of the cost of this system as applied to our own city we are accused of "overstraining license"! If we had gone out of our way to initiate a discussion on the relative merits of the two systems, we could, to some extent, understand Mr. Smith's indignation; but we have not done so. As many of your readers are aware, statements have been widely circulated to the effect that our process is more costly than that in use at Sutton. We do not for a moment suggest that Mr. Smith has so far "overstrained license" as to make any assertion of this kind; we merely state a fact which has again and again been brought to our notice. When the statement referred to found its way into your columns, coupled with an invitation to furnish figures on the subject, we thought it due both to your readers and ourselves that we should do so. So anxious, however, were we to avoid any misstatement of fact or injustice to the Sutton system that we sent a copy of our letter to Mr. Dibdin before publication. We would gladly have extended the same courtesy to Mr. Chambers Smith if we had had the slightest sus-

picion that he would have felt aggrieved by anything we had said.

Although Mr. Smith casts doubts on our estimate, even going so far as to question our competence to form an estimate, he has made no attempt to correct or contravert our figures. He has, indeed, given some very interesting particulars of the cost of the works at Sutton. We are fully aware that at Sutton the circumstances are peculiarly favourable for the construction of filters at a minimum of cost; and that the clay from the excavation for the filters served, after burning, as the filtering material. The Sutton Council are to be congratulated on their opportunities for doing work so cheaply, and on the skill with which these opportunities have been utilised. But is it fair to take a case in which these exceptional facilities exist, and because the cost per 100,000 gallons in this case seems to be somewhat less than at Exeter, to make the sweeping statement that the latter system costs more than the former? Surely the only fair way in which a comparison can be made is to place the two systems "on a common basis," as you yourself suggest in your editorial note. We therefore took a case with which we are well acquainted—that of Exeter—in which very careful estimates had already been prepared, and showed what the effect would be of substituting coarse-grain filters for the Septic tanks. In spite of Mr. Smith's strictures we consider that we are fully qualified to form an estimate of the cost of such works in Exeter; and we certainly yield to no one in our desire to do full justice to the Sutton system. Had we wished to state our case as strongly as possible there are several points on which we might fairly have made the comparison more favourable to ourselves.

We may add that we have compared the cost of tanks and filters in several other cases in which estimates have been prepared, and that the result which we have found in the case of Exeter holds good in every instance. Even where the contractor's price for filtering material is lowest, the substitution of coarse-grain filters for the Septic tanks would add very considerably to the cost of the works—that is to say, tanks and filters and royalty cost considerably less than fine and roughing filters alone. Our royalty, by the way, is not, as stated by Mr. Smith, fixed at 30 per cent.

With a view to meet Mr. Smith on his own ground, we will take his own comparison, that of Exeter with Sutton, as regards the main question at issue, viz., the relative cost of the tanks and the coarse-grain filters which replace them at Sutton. The tanks at Exeter will deal with 5,724,000 gallons per day; but in our letter we merely claimed the flow dealt with by both tanks and filters, *i.e.*, 2,500,000 gallons per day. The tanks will cost £3750, equal to £150 per 100,000 gallons, reckoned on the lower duty. No engineering is included; so, for the sake of comparison, Mr. Smith is entitled to add to the cost of the tanks engineering charges at the same rate as in his figures for Sutton. If the coarse-grain filters at Sutton are taken as costing only one-half of the cost of the installation, or £195 per 100,000 gallons, this is more by £45 (less engineering) than the cost of the tanks provided for the same work at Exeter. We do not attach much importance to this comparison, holding as we do that the only fair way to compare the two systems is to see what both work out at for the same case; but since Mr. Smith has chosen the method in question, we thought it right to show where it leads him.

He refuses to admit our suggestion that the cost of the tanks may be reduced under certain circumstances, but for the purpose of the comparison which he makes, we are certainly entitled to reduce the flow through the tanks from 5,724,000 gallons per day to 2,500,000. Their cost will then bear some reduction, though not in the same proportion. The extensive system of penstocks, conduits, &c., all of which are in duplicate, and laid out to pass the larger flow, will also be considerably reduced in cost, and the long by-pass conduit provided to carry the surplus 3,224,000 gallons past the filters would be done away with. Another possibility of saving which we had in mind in our remarks quoted under this heading was in connection with the expenditure included in the Exeter estimate for the protection of the works against floods.

(6) We can assure Mr. Smith that this point is a very practical one, as even the 2ft. necessary for the Sutton system are not always obtainable, and in such cases the saving even of 1ft. is an important matter. The reduction in fall would, of course, necessitate an increase in the area of the filters. If coarse-grain filters were adopted at Exeter, and we had to divide between two sets of filters the fall now available for the fine beds, the additional land over and above that required under the present scheme would cost over £2800, or more than three-quarters of the cost of the tanks. This is on the assumption that a certain cubic capacity of filter must be provided for a given amount of work, whether it be in a shallow filter or a deeper one. Possibly, in the shallow filter, a somewhat smaller quantity of filtering material would suffice, so that the area required would not be quite double that necessary with the deeper filter; but as we have not taken into account the extra cost of construction due to the larger area covered, the comparison seems to be a fair one.

(7) The cost of removing a few barrow-loads of screenings and disposing of them may seem small, but if it is capitalised, it will make a respectable total.

It is not fair to say, "under the Exeter system grit chambers are necessary," for where there is no grit, no grit chambers will be needed, and where large quantities of road detritus are swept down the sewers, they will be required, whether the Exeter or Sutton system be adopted. We trust we are not taking too much license in stating our belief that it is not desirable to fill up the interstices of a coarse-grain filter with road grit and mud. Nor do we see how Mr. Smith can justify his statement that "the cost of removal and disposal of the insoluble deposit in the grit chamber and the tank will . . . counterbalance the cost of screening, &c., in the Sutton system." Granting that the insoluble deposit in the tank will increase to such an extent as to require removal, it is obvious that a like amount of insoluble deposit in the interstices of a coarse-grain filter would render it absolutely useless. The removal of such deposit from a tank or a grit chamber is neither a difficult nor expensive matter; to remove it from the interstices of a filter would probably cost as much as a complete renewal of the filtering material.

In very small works the tanks are not in duplicate, as in such cases it will not be necessary to stop the flow into the tank.

(8) It was not necessary to state that the fine-grain filters at Exeter require an occasional raking

over, for the simple reason that this is common to both systems. The filters constructed of clinker only need this attention at intervals of several weeks.

In his 10th clause Mr. Smith says that "the Exeter system cannot be adopted under the existing rules of the Local Government Board unless land is also provided." (This, of course, applies equally to the Sutton system.) "This will require that a man be in attendance to cultivate it even in small works." Surely Mr. Smith does not mean that the small area of land necessary in such a case would need a man constantly in attendance.

In the cases in which the "attendance to the filters can be reduced to half . . . an hour or so per day," we presume that their working is not regulated with the same nicety which Mr. Smith would require in a larger installation. Be this as it may, our system would, even in such a case, effect a saving in labour alone sufficient to pay our royalty.

It is rather late in the day to say as in (9) that "time alone will prove whether the cost of this (our alternating gear) will be compensated by the assumed saving in labour and regularity of working;" and again, "it has yet to be discovered that artificial filters can be treated as automatic machines." These points have been fairly well established by the various chemists who have examined the working of the Exeter installation, and whose opinions are entitled to some respect at Mr. Smith's hands.

It is quite true that sewage varies in character from hour to hour during the day, and we are quite prepared to learn that Mr. Smith instructs the men employed on the night shift to make the period of contact shorter than during the day. But with our alternating gear there is no need for any one to be at the works at night. If it were necessary to vary the time of contact, the change in the alternating gear necessary to secure such variation could be made in a few minutes; but with the Septic tank no such change is necessary, because, in spite of the variation in the character of the sewage during the day, the effluent from the tank is approximately constant in character from hour to hour. The shortening of the cycle and consequent increase in the rate at which the filters work, is not due to the alternating gear, as Mr. Smith suggests, but to the variation in the flow. Whether alternating gear is used or not, the filters will have to work faster when they have a large flow to deal with. Here also the Exeter system has a marked advantage over that at Sutton, inasmuch as the Septic tank affords a means of storing the excess at the time of maximum flow, so as to give the filters the benefit of a uniform flow throughout the twenty-four hours. In the new works at Exeter this is provided for.

Mr. Smith has "one other objection" to urge against our alternating gear, namely, "that the discharge valve is opened its full diameter at the commencement, when the filtrate is liberated with a rush, carrying with it the fine material and fouling the filtrate." It is important to note that nearly all the samples taken for analysis at our works and reported on at the inquiry were taken during this rush. These samples, taken under all the disadvantages described by Mr. Smith, were decidedly better than those from an ordinary sewage farm, and fit to be discharged into any running stream. But if Mr. Smith requires an alternating gear which shall retain the effluent in the filter for any specified time, and which shall open the discharge valve slightly at the commencement, and gradually increase the opening as the discharge goes on, we need hardly say we shall be happy to supply him with such a gear.

We fully admit Mr. Smith's claim as to the superiority of the Sutton process over any of its predecessors, our own system excepted; and it is with no wish to disparage that process that we state as the result of careful examination that in every case which has come to our notice our own will be found the less costly.—Yours faithfully,

CAMERON, COMMIN, AND MARTIN.

7 and 8, Bedford-circus, Exeter,
16th March.

COST OF BACTERIA SYSTEMS.

SIR,—It is evident from Mr. C. Chambers Smith's letter, which appeared in THE SANITARY RECORD of the 11th inst., that the Dibdin process is more economical than the Septic system, and Medical Officers and Engineers should feel indebted to Mr. Smith for pointing out the danger likely to arise from the use of the Septic alternating gear. Mr. Smith points out that there is no royalty charge of 30 per cent. upon the cost of works when the Dibdin system is used; yet the *Leeds Mercury* of the 3rd ult. stated that the Leeds Council had paid Mr. Dibdin a little over £900 in fees for advice respecting the experimental installation for treating about 100,000 gallons per day, and that in future Mr. Dibdin was only to be paid 20 guineas a day when engaged at the sewage works, and 3 guineas for each analysis. Although these fees may appear high, they are probably considerably less than the Septic Company royalty charges would amount to; but it would be interesting if Messrs. Cameron could show whether their royalty charges on the Septic system are likely to be less than Mr. Dibdin's fees for advice.—Yours faithfully, SEWAGE ENGINEER.

SEWAGE PURIFICATION.

SIR,—This interesting problem is now so well ventilated that its solution seems to me in the near future, and particularly so as a Royal Commission is about to take the matter in hand.

Sewage farming has proved that in cases where the conditions are favourable sewage can be efficiently treated, and an effluent produced which gives general satisfaction, but unfortunately, for reasons quite independent of the principle, this system can never have a general application.

Chemical treatment, on the other hand, can be applied in every case, and if properly and scientifically carried out no system can cope with it as to results obtained. The only bugbear is the sludge, but I hope to prove very shortly that sludge can be made a marketable article, and be sold at a price in any case sufficient to cover all the working expenses of the sewage treatment.

The bacterial treatment of sewage has recently come to the front, and it could not be otherwise, patronised as it is by such an eminent authority as Mr. W. J. Dibdin. It is doubtful, however, whether it is not a violation of Nature's laws to allow such a rich and valuable material to be eaten up by

bacteria, instead of utilising it for enriching the soil, as it evidently was intended.

On the other hand, notwithstanding the extended trials at Barking, Sutton, Exeter, Yeovil, Leeds, Blackburn, and other places, no definite figures are forthcoming as to the cost. On this side, if an engineer proposes a scheme he stakes not only his reputation but also his purse. You will see then that it is necessary to have figures on which we can rely with confidence.

A scheme for sewage farming as well as for chemical treatment can be prepared now-a-days with sufficient accuracy, but such is not yet the case with the bacterial treatment. Even eminent chemists disagree as to the results obtained. Taking Exeter experiments as an example, we have a variation of from 11·2 free ammonia (Rideal) in November to 2·2 (Dibdin and Thudichum) in June. This result goes to prove that in the winter months, in order to obtain the same result as in summer, five times more filtering surface must be employed, and it would appear that no one has yet attempted the application of a principle which forms one of the claims in my patent to balance the work of the bacteria all the year round.

When a bacteriologist takes a sample of water or sewage for examination, he is careful to place it in a box filled with ice, to prevent the development of the bacteria, and he is certain that although the bacteria have an abundant supply of oxygen, still they remain torpid on account of the low temperature. When he arrives at his laboratory he inoculates his getitine or bouillon, as the case may be, with the water or sewage, and places his sample carefully in glass cases and in a specially heated chamber, which he keeps at a constant temperature of from 70 deg. to 75 deg. Fah. The bacteria, which were torpid at a low temperature, now begin to develope in the heated chamber, and in a very short time they become so numerous that it is impossible to count them. This laboratory experiment corresponds absolutely with the practical results obtained on a large scale at Exeter; that is to say, in summer the work of the bacteria is at least five times more than in winter.

In my patent I laid great stress on aëration, *but with heated air* to bring up the temperature of the bacterial filters to 70 deg. Fah., the temperature most suitable for the rapid development of bacterial life. All my experiments go to show that heat is as necessary as oxygen to enable the bacteria to complete their destruction of the organic matters.

The heat necessary can be obtained from the waste gases of the destructors or steam boilers, and even if it was necessary to erect a small furnace to heat the air, the expense is nothing compared to the results obtained, as it means an enormous reduction of the filtering area, and the bacteria are placed in a medium enabling them to produce the greatest amount of work in the shortest space of time, whether in summer or winter.—Yours faithfully,

ANDREW HOWATSON.

88, Avenue de Neuilly,
Neuilly-sur-Seine, près Paris,

NOTICE TO CORRESPONDENTS.

OWING to a pressure of space several letters are unavoidably held over.

Notes and Queries.

Subscribers have the privilege of obtaining advice in this column on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed to THE EDITOR, "Notes and Queries," THE SANITARY RECORD, 5, Fetter-lane, London, E.C 1

NOTE.—If an answer be required immediately, a stamped addressed envelope must be enclosed, when we will endeavour to furnish a copy of the answer by post, as owing to the large number of queries received we cannot guarantee the insertion of a reply in the succeeding issue.

1001.—HOUSE DRAINAGE: DRAIN OR SEWER.—"Dispute" writes:—(1) "In a block of back-to-back houses a rain-water pipe has been broken, and the rain-water runs in the foundations of Nos. 8 and 10, the houses belonging to two different owners. The pipe is fixed on the party wall, and runs through the houses from one side to the other. The owner of No. 8 says that the owner of No. 10 should repair the pipe, and No. 10 says it should be repaired at the joint cost of the two owners. To whom should I give notice to abate the nuisance? (2) A street gully which is fixed in the street and used for house drainage, and situate midway between the doors of two houses, is blocked up. Who should open the gully, the tenant or the owner? If the latter, which owner is responsible? Are these drains or sewers? The block was formerly owned by one owner, but now belongs to four owners. I may add that the common drains were laid by the Local Board about twenty years ago at the cost of the owners."

Answer. — (1) Inasmuch as the rain-water pipe is jointly used for the roof drainage of houses belonging to two different owners, its repair and maintenance should be borne jointly by the two owners, and a notice should be served on both under Sec. 94 of the Act of 1875. (2) The abatement of the nuisance will devolve upon the occupiers who jointly use the gully, and notice should be served on each under Sec. 94, or it may be served on one person only as provided by Sec. 255. Owners are liable for nuisances arising from the want or defective construction of structural conveniences, and tenants, generally speaking, are liable for nuisances caused by the improper use or misuse of such conveniences and for neglect to cleanse drains, cesspools, ash-pits, and the like. A gully used for receiving slop-water is not a sewer. The common drain will, we think, be a sewer, although if it be used for draining two or more houses within the same curtilage it may, nevertheless, be a drain. Decisions on the subject are very conflicting.

1002.—INSPECTORS OF FACTORIES: QUALIFICATIONS, &c.—"H." writes:—"Where can I find full information as to the requisite qualification and method of appointment of H.M. Inspectors of Factories, and the usual procedure in making application for the post?"

Answer.—We answered a similar Query, No. 994 in our issue of March 18th, to which our correspondent should refer.

1003. — WATER: TESTS FOR IMPURITIES IN.—"F. D." writes:—"I am instructed by my Council to take samples of drinking water in my district, which is obtained from rain-water tanks and wells, but as these are not for analysis I cannot see the use of taking them, and I should esteem it a favour if you could inform me of any simple chemical tests which would serve to show whether the water was contaminated or not by soakage from cesspools or other sources of pollution, which I could apply myself, when, if I found anything suspicious, I could then take a sample and submit it to a professional analyst."

Answer.—A simple test which can be recommended is Dr. Lowe's, described as a "Ready Test for Sewage Impurities in Water." To use the test one of the glass balls is dropped from a height of a foot into a clean wine glass the latter to be thereupon filled with the water to

be tested. The more dangerous kinds of impurity (ammoniacal products derived from sewage) if present in considerable amount are at once detected by the production of a yellow colour, or by a flocculent deposit which becomes yellow or greenish after standing six hours. Water of this description is unfit for use. If a cloudiness or white precipitate is formed, the water should not be used without previous boiling, and it should be submitted to a professional analyst. The tests are supplied at 2s. 6d. per dozen by Messrs. Negretti and Zambra, 38, Holborn Viaduct, London, E.C. Ready tests for ascertaining impurities in water are also supplied by the London and General Water Purifying Company, Ltd., 157, Strand, W.C. The company publish a pamphlet entitled "Water: Its Impurities and Purification," price 6d., wherefrom particulars and prices of the tests may be obtained. None of these tests must, however, be considered to supplant the requirements of analysis by a skilled analyst, but may be used for determining roughly the presence of impurities.

1004.—MEMBER OF DISTRICT COUNCIL INTERESTED IN CONTRACT: DISQUALIFICATION.—"C. C." writes:—"In your reply to Query 992, on above subject, have you not overlooked Sub-section 2 of Sec. 46 of the Local Government Act, 1894, which provides for a Councillor entering into a contract with the Council? At least, I understood it so."

Answer.—We are much obliged to our correspondent. The provision that a person shall not be disqualified for being a member or chairman of any Council when interested in a contract, extends only to the Councillor being interested in the sale or lease of any lands, or in any loan of money to the Council or Board, or in any contract with the Council for the supply from land of which he is owner or occupier of stone gravel or other materials for making or repairing highways or bridges, or in the transport of materials for the repair of roads or bridges in his own immediate neighbourhood. This exception, however, was not overlooked by us and does not apply to the case put before us in Query 992. The intention of the Legislature in framing this section was to avoid penalising members in rural districts, such as farmers who may possess gravel-pits or stone quarries, who might supply such materials where such could not otherwise be procurable except at considerably increased cost to the Highway Authorities for the repair of roads; and also to enable such Councillors to supply team labour for a similar reason. But in each instance, the supply of materials or team labour must be in the immediate neighbourhood of the residence or holding of the Councillor.

1005.—BUILDING BYE-LAWS: PLANS APPROVED BEFORE NEW BYE-LAWS WERE CONFIRMED.—"M. S." writes:—"Will you please inform me whether the last clause in the Building Bye-laws sent herewith, which repeals former bye-laws, exempts buildings the plans for which were passed but work not commenced before the new bye-laws came into force? What construction would you place on the word 'work' in the repeal clause?"

Answer.—Where plans for new buildings, have been approved by the Sanitary Authority under the old bye-laws and notwithstanding that the work is not yet commenced, such buildings will be exempt from the operation of the new bye-laws. The word "work" in the clause referred to must be read with the sentence immediately following, which, we think, our correspondent appears to have overlooked. The clause is as follows:—"The bye-laws . . . confirmed on . . . shall be repealed except as regards any work commenced before the date of confirmation of this bye-law or any work not so commenced but of which plans shall either have been approved by the Sanitary Authority before such date or have been sent to the surveyor or clerk to the Sanitary Authority one month at least before such date, and shall not have been disapproved by the Sanitary Authority."

1006.—HOUSE DRAINAGE: WATER TEST.—"S. P. K." writes:—"In applying the water test to a drain would it be right to fill, say, a 4in. drain 80ft. long, with a fall of 1 in 40 from plug to highest gully, which would give a head of 2ft? Would the pipes be fractured if even a greater head were given? I was told by a surveyor the other day, the pipes would be fractured, and he also said the water test was not a good one, because the lower pipes had to stand the most pressure."

Answer.—The hydraulic or water test for applying to new house drains is the best and most reliable test at present known to engineers, and is enforced by all Local Authorities of repute before the drains are covered in. It is incorrect to state that ordinary drain pipes would be fractured under an internal pressure of 2ft. head, or ·864 lb. per square inch. Many fire-clay pipes will withstand a pressure when one-twelfth of an inch thick, of 160lb. to the square inch, or a head of 69·28ft. Drains constructed of sanitary pipes and jointed with cement should be able to bear a pressure of at least 4ft. to 5ft. head of water without damage to the joint, if the latter is properly made. When it is required to apply the test to a considerable length of drain, square junctions should be laid at every rise of 4ft. for the introduction of the testing plug, so that each section of the drain may be tested separately.

1007.—OPENINGS IN PUBLIC HIGHWAYS: REPAIR OF SURFACE.—"M. S." writes:—"What is the custom with regard to builders and owners of property opening the surface of streets to connect drains to sewers or for repairs? Is there any statutory power to compel such persons to keep the surface of the roadway over such

drain good for a reasonable time, say six months, until all settlement has ceased? I enclose copy of form of consent given by this Urban Authority to open the road."

Answer.—It is the practice with very many Urban Authorities not to permit private individuals to open the surface of public highways for the laying or repairing of drains. In such cases the Authority undertake the necessary work but the owner or occupier of the premises is required to pay the estimated cost of the work in advance to the Authority. When this practice is not carried out the Urban Authority are enabled, under Sec. 149 of the Public Health Act, 1875, or under Local Acts in the case of boroughs, to withhold or give consent for the opening of the surface of the road on such conditions as they deem fit. The Authority may, in our opinion, reasonably require the surface of the trench to be maintained for a period of six months. The provisions of Sec. 149 referred to, as to wilfully taking up or displacing, or injuring the pavement, stones, materials, &c., of a public street in an urban district under penalties, should not be overlooked. In the case named by our correspondent, consent is given subject to the owner reimbursing the cost of any work which the Authority may have to bear in subsequently making good the surface of the street.

1008.—BUILDING BYE-LAWS: CONTRAVENTION OF.—"Surveyor" writes:—"A person deposited plans with my Authority for building a pair of shops, which the Committee passed, subject to their being carried out in accordance with the bye-laws. B, a local builder, is erecting them, and is contravening Bye-law 31 by placing timber in the party walls, and not leaving the 4½in. as stated by Bye-law 32. Moreover, the templates supporting the bressumers over the shop windows are of wood, which is not in accordance with Bye-law 33. These, I know, can be enforced. But the bressumer over the window is not strong enough, and is sagging in the centre about 1½in., although the work is only half-way towards completion. I have written the builder, saying he must put in stronger timbers, or strengthen the existing bressumer by fixing an iron column under it, or by any other approved method. Can I enforce this, and, if so, under what clause? In case of a prosecution, should proceedings be taken against the builder who is carrying out the work, or the owner who deposited the plans?"

Answer.—The builder may be required, under Bye-law 33, to provide additional support to the bressumer. The second paragraph of this bye-law provides that the person erecting a new building shall also, if necessary, cause such bressumer to have such other storey-posts, iron columns, stanchions, or piers of brick or stone on a solid foundation under the same, as may be sufficient to carry the superstructure. If the builder fails to comply with the requirement of the Local Authority who have called upon him, after being satisfied of the insufficiency of support to the said bressumer, they may take proceedings against him for a contravention of Bye-law 33. The Local Authority should be prepared with evidence to prove the insufficiency of the bressumer and the strength of same for resisting the pressure of the weight of wall above it. Proceedings should be taken against the builder, who is the person erecting the building, as provided by the bye-law.

BEVERLEY.—March 28th.—Clough Doors, &c.—Mr. W. Evans, surveyor, New-walk, Beverley.

HEBBURN.—March 28th.—Sewer.—Mr. J. B. Renton, Argyle-street, Hebburn.

LONDON, W.—March 29th.—Sanitary Alterations.—Mr. T. Hensman Munsey, vestry clerk, Vestry Hall, Piccadilly, W.

RUNCORN.—March 29th.—Sewering.—The Surveyor's Office, Town Hall.

IPSWICH.—March 29th.—Electric Lighting, &c.—Mr. A. G. Vulliamy, clerk, 6, Tower-street, Ipswich.

STANLEY (DURHAM).—March 30th.—Scavenging.—Mr. Joseph Routledge, surveyor, Council Offices, Stanley.

BATH—April 2nd.—Reservoir, &c.—Mr. E. H. Sheppard, surveyor, 3, North-parade, Bath.

BUXTON.—April 2nd.—Heating.—Mr. S. Selby, 21, High-street, Buxton.

CONGLETON (CHESHIRE).—April 2nd—14th.—Water-supply Works.—Mr. C. Russell Hall, West-street, Congleton.

BATTLE (SUSSEX).—April 4th—Drain.—Mr. Henry Card, county surveyor, County Hall, Lewes.

GLASTONBURY.—April 4th.—Sewer, &c.—The Borough Surveyor, Council Offices, Glastonbury.

PUDSEY.—April 4th.—Sewers.—Mr. J. Jones, surveyor, Council Offices, Pudsey.

EPPING (ESSEX).—April 5th.—Sewers, &c.—Mr. Edmond Egan, A.R.I.B.A., engineer to the Council, Holmdale, Loughton, Essex.

COMPETITIONS.

CRICKLADE (WILTS), April 30th.—Water Supply Plans.—The Cricklade and Wootton Bassett Rural District Council invite engineers to forward a report, with plans and estimates, for furnishing an effective system of water supply to the town of Cricklade, Wilts, exclusive of the cost of the land or easements, but inclusive of all other expenses. Premiums of £21 and £10 10s. will be given for the plans which the Council shall adjudge to be first and second in order of merit. Mr. Harry Bevir, clerk, Union Offices, Wootton Bassett.

WINCHESTER, March 31st.—Public Baths. Extension of Time.—The time for submitting plans for the public baths competition is extended to March 31st. Premiums of £25 and £15 will be awarded for the designs adjudged by the Council of sufficient merit, and placed first and second in order respectively. The premiated plans will become the property of the Corporation. Drawings and detailed estimate to be deposited at the office of Mr. Walter Bailey, town clerk, Guildhall, Winchester, marked "Swimming Baths," on or before March 31st, instead of 28th inst., as previously mentioned.

To Surveyors, Sanitary Inspectors, &c.—First-class Cycles at reasonable prices. Don't place your orders elsewhere until you have seen our post-free catalogue.—MELROSE CYCLE COMPANY, Coventry.

SCHERING'S NEW DIETETIC.

This is a new albumen preparation for domestic use. Its constituents, similar to milk, especially Human Milk, give it a peculiar value.

SANOSE

SANOSE is an odourless and tasteless white powder, forming an emulsion when stirred in water.
THE MEDICAL PROFESSION strongly recommends it in cases of Anæmia, Dyspeptic troubles, Consumption, and in Cachectic Women.

For literature see "THE THERAPIST," November, 1897, and January, 1898.

Price 1s. per ounce; 3s. 6d. per 4 ounces.

Apply to all Chemists and Druggists, or to **A. & M. ZIMMERMANN, 9-10, St. Mary-at-Hill, London, E.C.**

DR. TIBBLES' VI-COCOA.

ARTICLE NO. 1.

IGNORANT STATEMENTS REFUTED.

WHEN a happy idea occurs to an inventor there are always persons who are ready to disparage the discovery, especially if it cannot be imitated with success.

The introduction of a combination which possesses several advantages over ordinary Cocoa has met with such unparalleled success, that it has evidently aroused the jealousy of other Cocoa manufacturers.

The use of malt and hops in the form of beer is almost a characteristic of the British people, but the rapid spread of temperance principles has deprived many people of the use of these two valuable products in the form of a beverage.

It is difficult to make liquid preparations of malt and hops that will keep, without the use of alcohol or some other equally objectionable preservative Consequently the idea of combining them in a solid form with Cocoa, so that on the addition of water or milk they would form a beverage, containing the properties and possessing the advantages of all three, has naturally met with the success it deserves.

Kola is not so widely known as malt and hops, hence possibly the ignorant and erroneous statements that have been circulated by a badly informed writer, who does not sign his name, in an almost unknown medical journal, but which we regret to find have been quoted by a well-known firm of Cocoa manufacturers, as if the statements were true.

Kola has been carefully analysed by English and French chemists of the highest reputation. In any modern work on the chemistry of vegetable substances the information may be found that Kola contains the same active principle as Cocoa itself, viz., theobromine, as well as caffeine, the active principle that occurs in tea and coffee.

In most tropical and sub-tropical countries some plant or other containing these active principles has instinctively been chosen by the natives as a national beverage. The use of coffee, extending originally from Abyssinia and Arabia, has become more or less general over the civilised globe as a brain stimulant. The use of tea, originating in China and Japan, has also spread over the world, more especially in English-speaking countries and English colonies, more perhaps as a restorative and aid to muscular exertion than as a brain stimulant.

In the Argentine Republic and southern parts of South America millions of pounds of Paraguay tea, prepared from a kind of holly, are used similarly for making tea, and in northern parts of South America, especially in the districts of the Amazon, Guanana is employed for the same purpose. Throughout Western Africa, extending southward to the Angola and eastwards to the Soudan, Kola nut has been described by the earliest travellers, and up to the most recent date, as used by the negroes for the same purpose as tea. Indeed, the seeds have been carried by them in past times and planted in the West Indies and other countries where the negroes were taken as slaves.

All these substances contain caffeine as the active principle, but each differs in the presence of small quantities of other constituents, which cause the well-known difference in the effects of tea, coffee, and Paraguay tea. Tea is apt to cause indigestion and nervousness in some people, coffee is liable to produce constipation in others ; but Kola, whilst it has not the aroma of coffee or the fragrance of fine tea, is without the disadvantages of either, and, therefore, by its addition to Cocoa, gives to that beverage the advantage of caffeine as a restorative and stimulant without the disadvantages of either.

In proof of this statement, we may quote from a paper on Kola, by Dr. Daniell, who was for some time a resident in West Africa, and who says in the *Pharmaceutical Journal* (1865, Second Series, vol. vi., p. 450) : "One remarkable feature worthy of attention is the marked avidity displayed by the negro inhabitants of Sierra Leone and Portuguese colonies for the nuts in preference to the beverage of tea and coffee, although these contain the same alkaloid."

The Kola tree is nearly allied to the Cocoa tree, for both belong to the same family of plants, and contains the same active principle, but in smaller quantity, with the addition of as much caffeine as is found in good tea and coffee.

The *British Medical Journal* says : "Vi-Cocoa is a very palatable beverage of great stimulating and sustaining properties." The *Lancet* says : "Vi-Cocoa must be assigned a place in the front rank of really valuable foods, since it is the embodiment of all the numerous principles contained in Malt, Hops, Kola, and Cocoa ; . . . of distinct value as a restorative and stimulative food."

Merit, and merit alone, is what is claimed for Tibbles' Vi-Cocoa, and the proprietors are prepared to send any medical man on application (a post-card will do) a large sample tin of Tibbles' Vi-Cocoa free and post paid, also a little book containing the reports of the very highest medical experts and analysts in the United Kingdom, showing the advantages of Dr. Tibbles' Vi-Cocoa over all other food products.

Address—DR. TIBBLES' VI-COCOA, LIMITED, 60 61, and 62, Bunhill-row, London, E.C.

SITUATIONS.

VACANT.

☞ *Advertisements of Situations Vacant are inserted at the rate of Sixpence per line (prepaid), minimum three lines — eight words to line. Special rates for a series.*

WANTED.

THE SANITARY RECORD *will be found an excellent medium for those who are desirous of seeking Situations in the Offices of Surveyors, Sanitary Inspectors, Sanitary Engineers, Architects, &c. The charge for such advertisements (prepaid) is Sixpence per line. Minimum three lines—eight words to the line.*

☞ **Advertisements for this Department must reach us by Tuesday morning in each week, at latest.**

SANITARY INSTITUTE EXAMINATIONS.

TUITION BY CORRESPONDENCE.

An Engineer and Surveyor (Mem. San. Inst.), Certificated Surveyor and Inspector, prepares students for these Exams. by Correspondence through the post.

Fees strictly moderate. Cramming studiously avoided.

The course of tuition is arranged so as not only to qualify the student for passing the exams., but what is of equal importance, viz., that he may become a thoroughly efficient Inspector.

On successfully passing the exams., all possible assistance and advice is given to help forward intending candidates for public offices.

Many of my old pupils are now filling positions with salaries of over £120 a year.

For terms, &c., address "C. E.," care SANITARY RECORD, 5. Fetter-lane, London, E.C.

SANITARY ASSOCIATION OF SCOTLAND

EXAMINATIONS IN SANITARY SCIENCE.

Examinations for Certificates of Competency in Sanitary Science are held each year as follows, viz.:—In Glasgow in April, in Edinburgh in October, and at such other time and place as the Board of Examiners may determine.

Entrance Fee £2 2s.

For further particulars apply to

GEORGE MIDDLETON, M.A., LL.B.,
Writer, 92, Bath Street, Glasgow,
Secretary to the Board of Examiners.

A Stamped Addressed Envelope must accompany all letters requiring an answer.

SANITARY INSTITUTE EXAMINATIONS.

SPECIAL Corresponding Classes for the **Practical Sanitary Science,** and **Sanitary Inspectors' Examinations** of the **Sanitary Institute, 1898,** conducted by a gentleman holding appointments as Urban District Council Engineer and Sanitary Inspector, holder of three certificates from the Sanitary Institute, First-class Honour Medallist Hygiene, &c. Hundreds of successes.—For all particulars, testimonials, &c., apply Mem. San. Inst., Office of THE SANITARY RECORD, 5, Fetter-lane, London E.C.

OFFICIAL ADVERTISEMENTS.

COUNTY BOROUGH of SUNDERLAND.

INSPECTOR OF HOUSE DRAINS AND SANITARY FITTINGS.

WANTED, by the Corporation of Sunderland, an INSPECTOR, to superintend the construction and perform the testing of House Drains and Sanitary Fittings.

Salary £130 per annum, increasing by £10 yearly until £150 per annum be reached.

Candidates must have had a thoroughly practical experience in works of sewerage, drainage, and sanitary plumbing, and must hold the certificate of the Sanitary Institute.

The person appointed will be required to devote his whole time to the duties of the office, and may, in addition to the foregoing duties, be required to discharge those of an Inspector of Nuisances.

Personal canvassing for the appointment will be a disqualification.

Applications, in the handwriting of the candidates, stating age, residence, past and present occupation, accompanied by copies of not more than six testimonials of recent date, must be delivered to me on or before Thursday, the 31st March instant, endorsed, "Inspector of House Drains, &c."

By order,
FRAS. M. BOWEY,
Town Clerk.

Town Hall, Sunderland,
14th March, 1898.

COUNTY BOROUGH of SUNDERLAND.

INSPECTOR OF SEWERS.

WANTED, by the Corporation of Sunderland, an INSPECTOR of SEWERS.

Salary £140 per annum, increasing by £10 yearly until £180 per annum be reached.

Duties will include the supervision of the laying of all new sewers, and the relaying, repair, inspection, cleansing, and flushing of all existing sewers, &c.

Candidates must have had a thoroughly practical experience in works of sewerage and drainage.

The person appointed will be required to devote the whole of his time to the duties of the office.

Personal canvassing for the appointment will be a disqualification.

Applications, in the handwriting of the candidates, stating age, residence, past and present occupation, accompanied by copies of not more than six testimonials of recent date, must be delivered to me on before Thursday, the 31st March instant, endorsed, "Inspector of Sewers."

By order,
FRAS. M. BOWEY,
Town Clerk.

Town Hall, Sunderland,
14th March, 1898.

IMPORTANT ANNOUNCEMENTS.

WILL SHORTLY APPEAR IN THE

Sanitary Record

A SERIES OF ARTICLES

ENTITLED—

"THE CHEMICAL AND BIOLOGICAL EXAMINATION OF WATER,"

BY

C. G. MOOR, M.A., F.C.S.

These Articles, which have been expecially written for THE SANITARY RECORD by Mr. Moor, will be fully illustrated, and will embody the results of the latest researches on this all-important subject.

The writer holds a unique reputation as joint author (with Mr. T. H. Pearmain) of "Applied Bacteriology" and "Aids to the Study of Bacteriology," both of which works have received high encomiums from the *Lancet*, the *British Medical Journal*, the *Chemical News*, &c., and we have no hesitation in commending this new series to the notice of all Public Bodies who are interested in the purity of public water supplies.

A

New Series of Articles

BY

W. J. DIBDIN, F.I.C., F.C.S.,

Late Chemist to the London County Council, Author of "The Purification of Sewage and Water," &c.,

WILL COMMENCE IN

The Sanitary Record

AT AN EARLY DATE.

Mr. Dibdin has chosen for his subject—

"LIME MORTAR AND CEMENT: Their Composition and Analysis,"

And the Articles will prove invaluable to Surveyors, Municipal Engineers, &c.

The date of publication will be duly announced in this column.

NOTICES.

ANNUAL SUBSCRIPTIONS. — The Annual Subscription to "The Sanitary Record," paid in advance, is 12s. 6d. This includes postage, and a Copy of the Diary, post free.

SUBSCRIBERS RESIDING in SCOTLAND and IRELAND are requested to pay by P.O. and NOT by cheque. If cheques BE sent they must be drawn for 13s.

MSS. cannot be returned unless accompanied by a stamped directed envelope.

Advertisements cannot be inserted unless received before Four o'clock on the TUESDAY of each week.

All communications should be addressed to the EDITOR, at 5, FETTER LANE, London, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, Ld.

THE

Sanitary Record,

APRIL 1, 1898.

Notes.

Sanitarians at Dinner.

SELDOM has there been a more representative gathering of men eminent in sanitary science than that which was assembled in the Holborn Restaurant last week to celebrate the twenty-second anniversary of the Sanitary Institute. As we glance over the short list of names at the head of the report given in our pages, there is not one but what has made some mark in the army of Public Health workers; and those present

from kindred organisations demonstrated the high value placed upon the work of the Institute. One remarkable feature, however, permeated the whole proceedings. All the speakers were able to refer to the many ways in which progress had been recorded in sanitary science; but there was a consensus of opinion that greater things were yet to be accomplished. Unquestionably we are on the eve of great discoveries, and Lord Egerton of Tatton showed how keen is the interest taken in the problem of sewage disposal. Truly, never was a Royal Commission appointed to inquire into a matter more vital to the public good, and we are convinced that when it closes its labours it will recommend the superseding of old methods by newer, better, and more economical means. The Sanitary Institute may well be proud of its work, for it is, as Sir Douglas Galton said, owing to its "single-minded desire to convey to the nation a due appreciation of the value of sanitation" that the old order will shortly give place to the new.

The Motor Car as a Refuse Collector.

In many ways the existence of the motor car appears to be a perilous one. The "financial difficulties" through which it has to drive before it can reach the public streets are simply enormous, and similar ones have in times past strangled many a "good thing." But there is one branch of local administration in which it appears likely to find favour, and that is as a collector of dust and refuse. It has received a fair trial at Chiswick, and the reports given of its efficiency are of a most satisfactory character. Other metropolitan districts are, we learn, likely to give it a trial. For instance, the Surveyor of Chelsea, Mr. T. W. E. Higgins, Assoc. M.I.C.E., has, in the course of a special report to the Vestry, made an interesting comparison of the cost of the two methods—horse and cart *v.* motor van. He estimates the capital expenditure on the latter would be £320. To work this would require a driver and two dustmen, and their wages and necessary fuel and water would cost £6 5s. per week, or £325 per annum, or with depreciation a charge of £357 10s. Two horses and vans he puts down at £240. Working expenses are estimated at £6 18s. per week, or £358 16s. per year, or with depreciation £370 16s. The difference between the two may not appear great, but it is more than sufficient to pay interest on the extra money needed for capital expenditure on the motor van. It will be interesting to see if these figures prove correct, but we are of the opinion that 5 per cent. is not sufficient allowance for wear and tear of horses and carts. Experience demonstrates, we think, that 10 per cent. is the least that should be reckoned for such a purpose.

Statistics.

We hear much about the pollution of streams running through Lancashire, yet there are few people who realise the magnitude of the causes working to this end. An interesting report on the subject has just been issued by Mr. R. A. Tatton, Chief Inspector to the Mersey and Irwell Joint Committee. In this we are told that in the area of Mersey and Irwell watersheds there are seven county and eleven non-county boroughs, with a population of 2,474,000 and a rateable value of nearly £6,200,000. To this must be added sixty-two Urban and ten Rural District Councils, with a population of 761,933 and rateable value of £3,542,344. On the rivers Irwell, Roach, Irk, Medlock, and Mersey, there are no less than 410 manufacturing works. The trade refuse from these concerns must be enormous; yet, thanks to the watchfulness of the Joint Committee officials, "the improvement reported in 1896 has been maintained, and the bed of the river in its upper reaches is practically free from cinders." With regard to pollution by liquid sewage, the following particulars are of interest:—"In 1892 there were 74 Urban Authorities; now there are 80. . . . Of the 74, only 27 had works in operation in 1892. In January of this year there were 61 such Authorities with works in operation." Besides these, sixteen have works in progress, leaving only three unprovided for. The report also deals with the new sewerage proposals for Manchester and Salford.

A Record!

There are many people who think that some of our Governmental Departments still maintain a reputation for circumlocution and want of punctuality in their dealings with local affairs, but we venture to think the "record" for delay is at present held by France. Early in March the inhabitants of Paris were surprised and amused one morning at an announcement placarded throughout the city. It ran somewhat like this: "The public are informed that in execution of a Royal Ordinance passed on August 23rd, 1835, an inquiry is about to be opened as to the propriety of constructing at Clarenton a new reservoir." This opens up a nice little problem. If it takes sixty-three years after the proclamation of a Royal Ordinance to arrive at a decision to "hold an inquiry," how long will be wanted to consider any report the Commission may make? Then, granting the report is favourable, what period will be required for the construction of the reservoir? Will the twentieth century witness its accomplishment? After all, in some things, at any rate, we "do better in England."

A Good Word for English Public Life.

Just now there is a desire on the part of many of our neighbours to speak unkindly of the Britisher and all his ways. It is refreshing, therefore, to have one word of praise from across the Atlantic, and more particularly as it refers to the conduct of our local administrators. Commenting on the recent London County Council election, the *Nation* (New York) has the following significant words:—"Strange as it may appear to us, the question of the honesty or competency of the employés of the Corporation has not once been raised during the canvass. It has not been charged that any one was unfit for his place, or got it through favour or corruption, or through being the favourite of an old pugilist in Whitechapel or Southwark. No one seems to expect to get a place through the election. There is no 'slate,' no 'dead beat,' or saloon-keeper talking of getting his dues at last out of the public, or of being able to lay up something for his old age. The discussion seems to have turned entirely on public questions." It is regrettable to think that when we reverse the above, a picture is presented

of what local politics sometimes are in the States. We hope, however, the lesson of London will not be lost, and that very soon the papers of our sister land may be able to say the same of the administrative life of their own cities and towns.

The Plague in India.

It is singular to think how indifferent people at home are to the really terrible state of things that at present exists in Bombay; but that they are indifferent is, we fear, beyond a doubt. A brief telegram or two—sometimes only once a week—and an occasional question in Parliament, practically sum up all that is to be seen in the daily Press on this momentous subject. If a few lives should be lost in a riot, we indeed suffer from no lack of news; but of the hundreds of lives that are mowed down every day by the fell disease, and of the untold suffering of which the great city is full, how much does the public of Great Britain hear—and how much does it care? And yet things are growing steadily worse. The official returns for last week report 1259 deaths from plague during the week, including four Europeans; the deaths from all causes numbered 2268, and the death-rate was 142·25 per 1000. The spread of the epidemic among Europeans gives us cause for grave anxiety. We observe, too, that the popular unrest, though outwardly suppressed, is as strong as ever.

The Small-pox at Middlesbrough.

It is somewhat disheartening, in view of the cheerfully optimistic tone that has for some time been held by the authorities at Middlesbrough, to observe in the daily reports of the small-pox epidemic how the loathsome disease continues to maintain its ground, in spite of the admirable sanitary arrangements that now prevail. On the 19th ult. seventeen cases were notified, on the 22nd there were nineteen, on the 24th there were twenty-five, and on the 25th there were seventeen, and, with very few exceptions, these were almost all from new centres; so that the end of the week does not find us much further forward than we were at the beginning. Altogether the number of cases since the commencement of the outbreak is now running well up to 1200. Several deaths occurred in hospital during the week, but, on the other hand, a large number of patients were discharged as cured, and a yet larger number are reported to be convalescent. There are still, however, about 400 cases in the wards.

Effects of the Epidemic.

We hear that the trade of the town is suffering terribly in consequence of the continued prevalence of the disease. A regrettable feature of the epidemic is the number of cases that has occurred among the men who have been employed in connection with the erection of the sanatorium. Another feature, that has its humorous aspect as well, arose in regard to the precautions taken in arranging a football match between Middlesbrough and Thornaby. The committee who had charge of the arrangements decided that the game should take place on a specially selected ground, with closed gates, and that only players who produced medical certificates as to their freedom from small-pox should be allowed to take part—so wisely careful were they that the infection should not be spread by a friendly game. Meanwhile the town authorities continue to exercise the utmost vigilance. One householder who has been detected in attempting to conceal a case of small-pox in his house is to be prosecuted. We trust that the hopeful view they take of the situation will soon be justified by a perceptible decline in the epidemic.

The Opposition to the New Vaccination Bill.

The Anti-Vaccinators are in a state of great indignation over the new Vaccination Bill. As we should expect, they insist that the only reform that will meet their views is the total repeal of the Vaccination Acts, and in particular they express their strong condemnation of the disregard by the Government of the Royal Commission's recommendation that conscientious objectors to vaccination should not be subjected to prosecution. These so-called "conscientious" objections, however, when closely examined, are beyond a doubt largely sentimental in character; and though some of them are undoubtedly based on real defects in the existing law, both classes of objections will be substantially obviated by the provisions of the new measure. The substitution of glycerinated calf lymph for human lymph, the extension of the age of compulsory vaccination, and the proviso whereby children may be vaccinated in future at their own homes, instead of at a public institution, all combine to remove the risks that may attend the present practice. They will, further, render it impossible for parents to attribute to vaccination those ailments which are incidental to infancy, or which have been contracted through hereditary transmission, or infection from other sources.

The Administration of the Act.

The Bill proposes no change in the Local Authority charged with carrying out the law. We may therefore expect that in many places, where anti-vaccination feeling is strong, it will continue to be made a test question of elections of Boards of Guardians, whether the Act, the administration of which is entrusted to them, is to be enforced or not; and it is possible that even the new Act will in some cases be allowed to remain a dead letter. This is to be regretted; but we trust that, with the great reforms that the measures will effect, a more enlightened opinion will prevail, until vaccination becomes practically universal. Some critics of the Bill have suggested that it would have been well had the Government adopted revaccination as part of their administrative duty towards the public. The time for this reform is probably not yet sufficiently mature, though we may look for it some day. There is no such educator of public opinion as an epidemic.

The Vaccination Bill and Scotland.

The Act is not to extend to Scotland or Ireland, but there is little doubt its influence will soon be there felt. The use of glycerinated lymph will probably become general before long, and when it is available human lymph will fall into disuse. The objections to repeated prosecutions, too, are not confined to England; so that, without express legislation on the subject, it is reasonable to expect

that Scotch and Irish practice will gradually assimilate itself in this respect to English law. As to the vaccination period, it was pointed out in the House of Commons last Friday that the maximum period in Scotland is at present six months; and if the period in England is to be extended to twelve months, Scotch members would naturally desire to obtain a similar extension for the northern half of the kingdom. The Lord Advocate, however, explained that there was really no need at present for fresh legislation for Scotland, because the power possessed by Medical Officers —if a child is not in a fit state for vaccination—to extend the period by means of a certificate for a period of two months, and thereafter, if necessary, to grant a still further extension of the period of exemption, obviates any feeling of hardship. The Scotch system on this point has always worked with perfect success.

Edinburgh and District Water Bill.

A SELECT Committee of the House of Lords, presided over by the Duke of Richmond and Gordon, have commenced consideration of a Bill for increasing the water supply of Edinburgh and district. The history of the Bill is curious, and we may have occasion to revert to it at another opportunity. In the meantime it is sufficient to state that it is the product partly of the great scarcity of water from which Edinburgh has suffered for some time past, and partly of a protracted litigation with the owners of certain mineral seams through which the city water pipes are carried. The straits to which Edinburgh has recently been reduced for obtaining an adequate water supply are not generally known. Sir Henry Littlejohn, the Medical Officer of Health, stated to the Committee that the position of affairs last summer was so serious that in the city hospital for contagious diseases, where there was then a large number of cases of scarlet fever, water could not be had to give the patients a bath. The situation was, indeed, perfectly scandalous; but the authorities kept it quiet, fearing that, if it were known, the reputation of the modern Athens would be seriously imperilled during the tourist season.

An Improvement Scheme for Edinburgh.

EDINBURGH has also been looking to further its sanitary reputation by the promotion of an improvement scheme having for its object the demolition of certain insanitary areas in the city in the districts of Stockbridge and Portobello. An inquiry ordered by the Secretary for Scotland under the Housing of the Working Classes Act has been held, at which it was stated that previous improvement schemes and various railway operations during recent years had considerably curtailed the supply of houses for the working classes; and, therefore, the Local Authority were quite prepared to recognise that the displacement of population necessitated by the present scheme might impose on them an obligation to provide new houses of a suitable kind. As for the need for this particular scheme, the evidence clearly showed that the properties proposed to be dealt with were not merely in a very dilapidated condition, but also overcrowded to a dangerous extent. In one area, of an acre in extent, there were 476 inhabitants, which was ten times more than the average rate over the city. Many of these houses were also most unsanitary, and some, which occupied very low levels and were near the shore, were liable to be flooded in high tides or after heavy rain—a state of things which pointed to the need for a permanent improvement.

Sewage Purification.

THERE is no subject at the present time in connection with municipal engineering which attracts more attention than that of sewage disposal and purification, which arises from the fact that many of the older systems—some of which were announced at the time of their introduction as affording a final solution of the difficulty of sewage treatment—have broken down in practice, and Local Authorities have been compelled by Rivers Boards or County Councils to take measures to ensure more efficient purification of the effluent from their sewage disposal works. Most of the patented processes have been unable to stand the test of many years' working; and treatment by land irrigation, so uniformly enforced by the Local Government Board, has also been found ineffectual in probably the majority of instances. The Report which is just published of the Rivers Committee of the Manchester Corporation—a sub-committee of which have been visiting numerous sewage works in the kingdom—is useful evidence at the present juncture of the failure of the old order of things, and of the transition which is taking place in the methods of purification of sewage. The deputation visited the Barking outfall works, Friern Barnet, Sutton (Surrey), Chorley, Oldham, Swinton, Salford, Glasgow and Accrington, and Church sewage disposal works, and it is interesting to note that at each of these places biological filters were found to have been constructed, and gave good and satisfactory results. The Committee observe that, "wherever they have visited the works of other Authorities in all cases the land is ineffective, and is in many cases to be superseded by artificial methods of filtration." The outcome of the labours of the Committee of the Manchester City Council is, that having considered the cost, capacity, and endurance of biological filters and bacteria beds, they recommend the construction of four acres of such bacteria beds, and that after completion of this area and proof of cost, capacity, and efficiency, the progressive extension of the same be made on an area large enough to meet the requirements of the daily normal flow of sewage. Such a conclusion, arrived at after most careful investigations by so important an Authority as Manchester, is likely to be copied by less important Local Authorities who have not the advantage of obtaining such information and advice as Manchester can afford. The report is a most valuable one, and we hope to be able to refer to it again later on.

TO OUR READERS.

The Editor solicits the co-operation of readers in making THE SANITARY RECORD *more attractive by means of pen-and-ink sketches, photographs, and diagrams. There are many phases of sanitary work which lend themselves admirably to illustration. By this means not only individual articles, but the journal as a whole will be heightened.*

NOTES ON PRACTICAL SANITARY SCIENCE.

By WILLIAM H. MAXWELL.

Assistant Engineer and Surveyor, Leyton Urban District Council, Author of "Drainage Work and Sanitary Fittings," "Ventilation Heating, and Lighting," &c., Certificates of the Association of Municipal and County Engineers, and Sanitary Institute.

No. 55.—REFUSE DESTRUCTORS.

(*Continued from page* 306.)

The Beaman and Deas Sludge Furnace.[137]

Messrs. Beaman and Deas have also a further patent furnace for burning sludge from sewage works, from manufacturers' settling tanks, and the slurry or slip produced in the manufacture of Portland cement and other similar materials. The construction of the furnace is illustrated in the accompanying Figures (22 and 23), in which

A = a reverberatory arch,
B = the fire-grate,
C = the inclined feeding hearth,
D = a hollow fire-bridge,
E = a perforated screen,
F = a secondary combustion chamber,
G = the ashpit, which is closed and provided with a forced draught through the air conduit H.

At the back of the secondary combustion chamber is an auxiliary chamber flue or passage I, communicating through flue J with the space K under the inclined feeding-hearth. In this space (K) a bridge L is erected for the purpose of deflecting the hot gases upon the under side of the feeding hearth, from whence they make an exit through a flue M to the chimney shaft.

The feeding-hearth consists of flanged angle bars arranged closely together and connected by bolts or rivets passing through the flanges.

Instead of allowing all the furnace gases to pass directly over the bridge D, some of them may be taken from a point over the inclined feeding hearth into a scondary combustion chamber through the hollow bridge, where they mingle with the incoming air, or the gases may be conveyed from the upper part of the inclined hearth direct to the secondary side of the furnace.

These furnaces may be built singly or in groups similar to ordinary destructor cells. The sludge or refuse material to be burnt is supplied to the upper part of the feeding hearth through a small opening (O) about 18in. square, which aperture is kept closed by the supply of refuse whilst the furnace is in use. The material thus supplied to the hearth is dried in the course of its downward passage to the grate, thus assisting its more rapid combustion. At P is a door through which the grate may be cleared and the clinkers removed. Dust is removed from the ashpit through door R, and from the flues and chambers below the furnace and hearth through S and T. Fresh air is supplied to the hollow bridge through the passages U. The products of combustion from the furnace, after passing the perforated screen, are caused to return through suitable flues to below the inclined feeding hearth, which becomes highly heated thereby.

Should there be no combustible matter in the sludge, &c., to be burnt, a sufficient quantity of breeze or other suitable combustible material is mixed with it.

The novel points claimed by the patentees for this type of furnace, in brief, are as follows:—

(1) The provision of a chamber or space below an inclined feeding hearth, into which chamber the hot gases from the furnace are led in such a manner as to impart their heat to the hearth.

(2) An inclined feeding hearth having a sinuous or zigzag cross section, and having also a space below it into which the products of combustion are led.

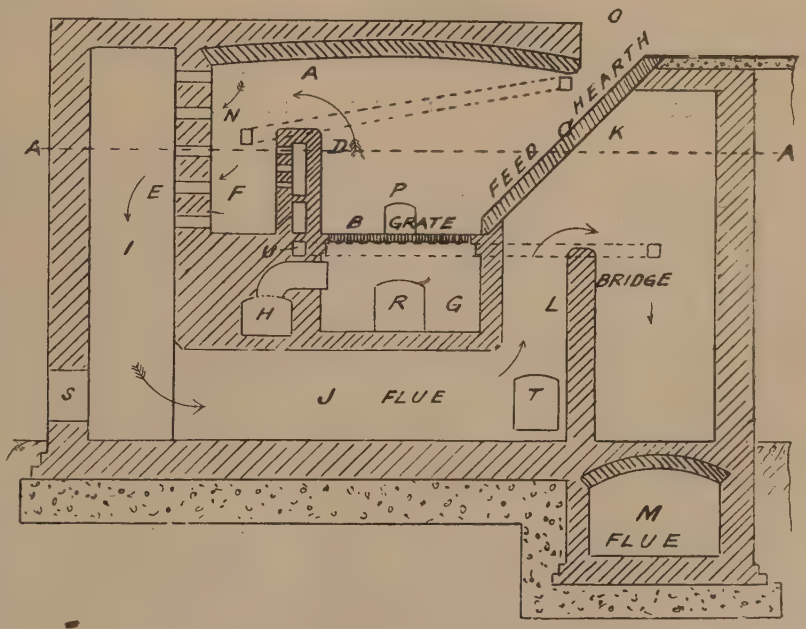

Fig. 22.—Section of Beaman and Deas's Sludge Furnace.

(3) Passages or flues connecting the interior of the furnace near the upper part of the hearth with a hollow fire-bridge or a secondary combustion chamber.

Hanson's Destructor and Utiliser.

This is a recent invention of Mr. John Hanson,

[137] Patent No. 13,029 (1894).

of Wakefield. The main points claimed for the apparatus are as follows:—

(1) A total absence of all fumes.
(2) Cheap first cost.
(3) A large capacity for given cost.
(4) It occupies small ground space for given capacity.
(5) It leaves a residue easily disposed of, and in certain cases saleable.
(6) The cost of treatment by it compares favourably with that of any other system.

The absence of fumes, it is stated, is attained by drawing, from the retorts, the fumes and steam given off by the stuff in drying and forcing them *under* the furnace bars with the forced draught.

A complete set of three Hanson retorts, with boiler in one setting, over three furnaces, with the necessary engine, shafting, screws for conveying material through retorts, riddles, elevators, chimney, &c., cost £1000 erected and ready for work in any part of England. The capacity of this set, as measured over twenty weeks' working at Wakefield, is two tons per working hour, or a capacity of 48 tons per twenty-four hours; and deals with ash-bin refuse, midden stuff, offal, and garbage.

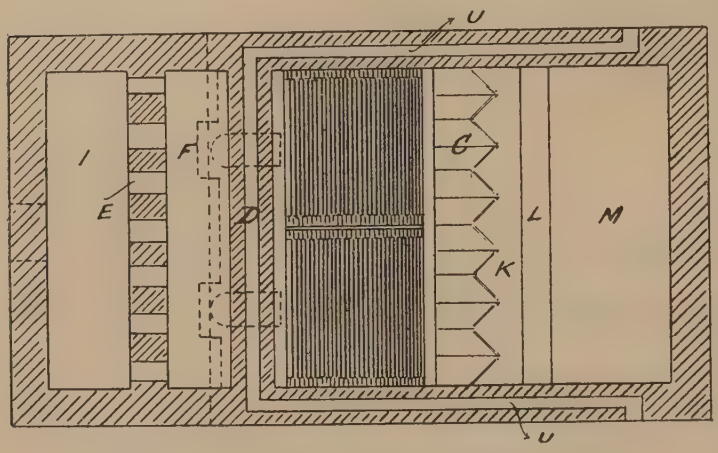

Fig. 23.—Plan of Beaman and Deas's Sludge Furnace.

The ground space occupied is comparatively small. A set of three Hanson retorts (as at Wakefield) measures 17ft. long and 12ft. deep, *i.e.*, it occupies a space of 204 square feet for a capacity of 48 tons per twenty-four hours.

The amount of clinker produced is said to be about six tons per 100 tons of refuse dealt with.

At Wakefield the cost of disposal is given at 1s. 3d. per ton.

Further, as bearing upon the question of economy, it is claimed that the Hanson destructor—requiring no expensive chimney or foundations, occupying little space, having large capacity, and working without smell or nuisance—lends itself to a system of small isolated destructors, each dealing with the refuse of the adjacent district, and so minimising cost of cartage of the refuse. It would appear, however, under such a system, that the cost of management and working must necessarily be increased in proportion to the number of such stations.

The above apparatus was also erected for the Corporation of West Ham.

From a report[138] of a deputation of the Board of Works for the Wandsworth District appointed to visit places in which dust destructors are in use, it appears that Hanson's apparatus was considered by the deputation, and that Mr. Hanson made the two following offers:—

(*a*) To treat the town refuse, not less than 140 tons per week, at a rate of 1s. 3d. per ton; the Board to pay 1s. 3d. per ton for the clinker that they require; the Board to provide land, weigh-bridge, and buildings of a temporary nature, and to collect the dust and deposit it day by day near the utiliser. The account to be paid monthly. He guaranteed to clear away all the surplus at his own cost, and that there should be no nuisance from the process.

(*b*) To erect for £1000 *one machine* called a "*utiliser*" to dry the cinders for fuel and the ashes for bricks and mortar; *two destructors*, side by side, to burn paper, rags, bones, dead animals, door-mats and bedding, also to melt the tin of meat cans, &c.; *one machine* to crush the tins for hard core or old iron.

He stated that the power from the machine and destructors would be 40 indicated horse-power, which would be available for mortar grinding, &c.; and that the above plant would deal with 80 tons per day.

Mr. Hanson was questioned on various matters connected with his method, and he stated that he only required a chimney some 25ft. high, from the top of which neither smell, smoke, or smuts would issue, as all the offensive vapours pass through a second fire. The rubbish generally would be sifted by machinery, and the feeding of the utiliser would be done by mechanical elevators. The destructors, however, which would consume the larger material, would have to be fed by hand.

At West Ham six men were employed to deal with refuse at the rate of 60 tons per twenty-four hours; that is to say, if three shifts of men were employed it would mean eighteen men to deal with 60 tons in twenty-four hours. Mr. Hanson stated that with improved plant labour could be considerably reduced.

"Smoke" is greatly troubling the inhabitants of Bombay. The Chairman of the Bombay Chamber of Commerce declares in his annual address that so little notice is taken of this growing evil that the "beautiful" island is fast becoming a smoky manufacturing district. He says:—"It is surely undesirable, to put it mildly, to allow these mills, ever increasing in number, to go on polluting the air to the utmost bent of their pleasure. It certainly cannot add to the salubrity of the city, and I think the matter is sufficiently aggravated for it to be seriously taken up."

[138] Dated May, 1897.

THE PROPER USE OF LAND IN CONNECTION WITH SEWAGE PURIFICATION.

By W. J. Dibdin, F.I.C., &c.

The best means of employing land for the final purification of sewage has been much debated, but in no case does it appear, so far as I am aware, that the question has been discussed from the correct point of view. In every instance it has been attacked with the view of showing that the land should be employed for the sole purpose of purifying the sewage, rather than with the object of utilising to the fullest extent the agricultural virtues of both land and sewage. Under the conditions of "broad irrigation," or compulsory "effluent farming," the former position was a necessity, as without the fullest effect of the land upon the sewage, the resulting liquid was not fit to be discharged into the stream, and it had either to be sent in unpurified, or on to the land under all climatic conditions, and often to the detriment of the crops.

The recently-introduced bacterial processes of sewage purification have placed the question upon a new footing in consequence of the high degree of purification obtainable without loss of the manurial constituents to the effluent, and the fitness of the liquid to be discharged into any stream, should it be deemed advisable to divert it from the farm.

Under the conditions of broad irrigation, or of land treatment by a chemical effluent, the water is charged with a certain amount of flocculent matter. When this is spread over the land day after day a matted deposit is formed on the surface, which produces clogging of the pores of the soil, or "sickening" at an earlier or later period. Every gardener knows the great importance of freely hoeing the ground in order to "promote growth;" in other words, of allowing the ground to *breathe*. Nothing is more fatal to free vegetation than daily watering the ground, in hot weather especially, without equally frequent hoeing, and thus causing the soil to cake either into a hard, close surface, or, in the case of too much water, turning it into a dismal swamp equally impervious to air. As the frequent hoeing of acres of farm land would be all but impracticable on account of the expense, it becomes a matter for question as to whether the desired result cannot be equally well or even better attained by other means, and with this view I venture to submit the following considerations upon the point.

In watering soil, undoubtedly the best way is to arrange so that the liquid is absorbed into the ground by capillary attraction without disturbing the surface, which would thus remain open and friable, and consequently in the best "breathing" condition. This result can be attained by first ploughing the ground, and, if it be of a clayey nature, applying a plentiful admixture of ashes, and then cutting trenches or furrows at right angles to the declivity, say every ten yards apart. Between these trenches, down the length of the beds, as the intervening ground may be termed, agricultural drainage pipes may be laid at a proper depth, just below the level of the bottom of the trench, or deeper if the subsoil is of an open and porous character. The seed or plants should be sown or set on these beds, and a daily charge of effluent, free from suspended matter, such as that yielded by the fine coke breeze beds worked on biological principles, turned into the trenches. This clear water will be soaked up by the intervening earth, which will thus be kept moist in a degree exactly suited to the exigencies of plant life, and the excess of fluid will find its way laterally through, say, five yards of soil, to the drainage pipes, thereby undergoing further purification in a thoroughly effective manner.

When the climatic conditions are such as to render the application of the effluent to the land inadvisable, it can be sent direct into the river, as the degree of purification already effected in the bacteria beds will be ample. By so doing the manurial constituents in the liquid, viz., the phosphoric acid, potash, and nitrogen, will not be employed on the land, but as the water will not be exerting its functions in "drowning" the land, they will be at least doing no harm. The great advantage of the bacterial system of treatment is that the nitrogen and other matters in their original foul condition are converted into a state in which they are best fitted for the support of vegetable life, just as they appear in an artificial manure. The process which takes place is precisely that which the farmer and gardener employ when they allow their crude, fresh manure to "rot," as they term it. Until this is accomplished they do not think of spreading it on the land. In the same manner, the crude sewage matters are allowed to undergo a process of "rotting"; in other words, disintegration and oxidisation by bacterial agency, in specially prepared beds.

In consequence of the freedom of the bacteria, or "filter," bed effluents, from suspended matter, the trenches will remain pure and sweet, and the land will not become choked with foulness, commonly described as "sickened," and thus with the exercise of proper care the process may be continued indefinitely with the greatest success.

As an instance of what may be done in this way, the experiments made last summer in mint growing at Sutton, Surrey, under the direction of Mr. C. Chambers Smith, the Engineer and Surveyor to the Council, may be quoted. The land was laid out as above described, planted with the ordinary field mint, and irrigated in the trenches, a small plot at the head of the field receiving effluent on the surface in the usual way. The crop of mint obtained was one of the finest I have ever witnessed, except in that portion which received the effluent on the surface. Here the plants were far between, stunted, and scorched up in appearance, whilst those in the beds between the trenches were thick and tall, full of leaf down to the bottom of the stalk, the whole presenting the appearance of dark green beds, on which a giant might recline in luxurious ease.

The financial result was that after paying for the cost of its distillation, the yield of oil of pepermint was sufficient to realise a profit of £20 per acre.

From this experiment it is clear that irrigation over the surface is a great blunder when a good effluent is obtainable, whilst irrigation by means of bed and furrow is not only most efficacious, but profitable in no small degree.

If land can thus be made to yield such a profit, the action of the Local Government Board in insisting upon the provision of a suitable area can be made to turn out to be of the greatest service to the ratepayers. Under the generally existing conditions sew-

age farms are a great loss and inconvenience, and are viewed with widespread dislike by the public at large. The arrival of the bacterial system on the scene promises to reform the old bugbear and turn our land into smiling fields absolutely free from all suspicion of cause of complaint. In the place of sodden ground yielding nothing but rank grass and evil-smelling miasma, we shall have dry top soil covered with a healthy vegetation, the leaves of which have never known sewage, nor the roots either, for the liquid which reaches them will no longer deserve that name. The productive power of the land will be greatly enhanced, and the atmosphere kept as sweet as if no such thing as sewage had ever troubled a much-puzzled committee.

What splendid pastures could be grown in this way, far exceeding in quality and beauty those obtained by surface irrigation. It is becoming more and more clear every day that now we are at last fairly and honestly following the indications of Dame Nature, she is rewarding us with an insight into the possibilities of her system far exceeding the most sanguine anticipations of the past. The cry has been, "Why waste the good manure?" The bacterial process, followed by irrigation, answers, "The manure is here in the best condition, and this is the way the land uses it." Millers want the water turned into the streams above their millrace. The bacterial process jumps to the call and says, "Here is the water, fresh and sweet, and ready for its work." There is no need to spread it over vast acres, and to discharge it below the mill, when in dry weather it is so much wanted above.

Let us then be up and doing, heave the old messy processes overboard, and start forward on the path of true progress with a firm step, stout heart and steady eye, and in a few years' time this question will have been settled for good and all, and our children will wonder how it was we could ever have been so stupid as to produce that embodiment of nastiness called "sludge."

UTILISATION OF REFUSE AND WASTE PRODUCTS.

AMONG the numerous waste products of factories which contribute to the pollution of our streams and rivers, the organic and putrescible refuse from breweries, distilleries, starch works, paper mills, and sizing works are not the least offensive. In Germany a lucrative industry has arisen from the conversion of these matters into a valuable fodder or cake for cattle, pigs, and poultry; damaged wheat, and, in short, anything consisting of starch, sugar, albumen, gluten, and the like, being equally acceptable, alone or mixed. One company at Cassel has for years made enormous profits, in 1895-6 paying a dividend of 38 per cent. on a capital of £75,000, which it has twice doubled since that time, the present paid-up capital standing at £300,000, and last year the dividend paid was 50 per cent., the 100 mark shares selling at 639 m., while from the *Frankfurter Zeitung* of February 9th of this year we find that they are now quoted at 650. This company works under Hencke's patent, his machines being also used by many brewers, distillers, and other manufacturers in their own works. The progress made by the Casseler Drying Company may be judged from the fact that the turnover, which in 1893 was £1,270,546, has risen year by year, until in the first nine months of 1897 it amounted to the almost incredible sum of £7,720,802. We do not wish to play the part of a financial journal, but we must, in a matter which really has a bearing on the public health as well as on the national wealth, express our satisfaction at learning that a company has been formed in this country which, by securing Hencke's patent, together with Cunliffe's, proposes to carry out not only the work of that at Cassel, but also the manufacture of manures from materials the composition or putrescent state of which unfits them for conversion into food for animals, with every prospect of making even larger profits than their German forerunners.

THE SANITARY INSTITUTE.

ANNUAL DINNER.

ON Wednesday, 23rd March, 1898, the annual dinner of the members of the Sanitary Institute, was held in the Throne-room of the Holborn Restaurant. In the unexpected absence of H.R.H. the Duke of Cambridge, the President of the Institute, the chair was taken by Sir Douglas Galton, K.C.B., D.C.L., LL.D., F.R.S., the chairman of the Council, and among a large distinguished and representative company were Earl Fortescue, Earl Egerton of Tatton, Sir E. Galsworthy, Sir Joseph Fayrer, Bart., Sir Arthur Blomfield, Major-General Carey, Dr. R. Farquharson, M.P., Sir Henry Thompson, Sir W. Guyer Hunter, K.C.M.G., Professor Corfield, Dr. Sims Woodhead, Professor H. Robinson, Dr. A. Whitelegge, Dr. W. Garnett, Mr. G. J. Symons, F.R.S., Dr. A. Wynter Blyth, Dr. G. V. Poore, Dr. F. Vacher, Professor H. Adams, Mr. Rowland Plumbe, Dr. Dawson Williams, Dr. A. Newsholme, Dr. J. F. J. Sykes, Mr. T. W. Cutler, Dr. Louis Parkes, Major Lamorock Flower, Dr. W. A. Bond, Mr. Lewis Angell, &c. &c., with Mr. E. White Wallis, the secretary.

The loyal toasts having been duly honoured,

Sir JOSEPH FAYRER, K.C.S.I., proposed "The Navy, Army, and Auxiliary Forces," and said the Sanitary Institute had special relations with the public services, or, at all events, with those exalted personages who represented them. Had H.R.H. the Duke of Cambridge been present he would gladly have offered him their grateful thanks for all H.R.H. had done for their institution and his advocacy of their claims for general support to their cause from its commencement. The Sanitary Institute was deeply indebted to the public services which had contributed to its development and advancement, and it would be a dereliction of duty on his part not to remind them of the great services rendered to it by the distinguished officer who occupied the chair that evening. Having long known from practical experience that their chairman represented sanitary engineering in the highest degree, he had no hesitation in saying that Sir Douglas Galton had done much for the Institute, and that as President of its Council he was one who had conferred an inestimable benefit, not only upon the civil population, but also to the military population of the country, and was entitled to their grateful acknowledgments. Among

others who had helped them were the late Professor Parkes, the late Sir Thomas Crawford, Professor Lane Notter, Inspector-General Macdonald of the Navy, and Sir W. Guyer Hunter. (Cheers.)

Major-General CAREY, in responding, said that in regard to sanitary matters he thought the Army had kept pace with the times. Enormous improvements had been made both as regards barracks and hospital accommodation in all sanitary requirements essential to the health and well-being of the soldiers. (Hear, hear.)

Sir ARTHUR BLOMFIELD gave the toast of "The Houses of Parliament," and pointed out that all their efforts in the direction of sanitary reform and improvement, in which they were all so much interested, and to which they devoted so much time, attention, and energy, were ultimately dependent upon the will of the two Houses of Parliament, without whose permission their measures could not be carried, and sometimes the means could not be provided to carry out those great works in which they felt so much interest. (Hear, hear.)

The Right Hon. EARL EGERTON OF TATTON, in responding for the House of Lords, said he had served his sanitary apprenticeship under the late Lord Aberdare on the Commission on Noxious Vapours. He had also in his capacity as landowner various opportunities of carrying out those sanitary reforms current during the last twenty-five years. In this respect a very great burden had been thrown upon the House of Lords as representing the landowners of the country. He did not say that there might not be exceptions, but speaking generally, he believed the members of the House of Lords had endeavoured to loyally carry out in those buildings over which they had control those sanitary requirements recognised as just. He could not say, however, that all these questions had been satisfactorily solved yet. From his connections with Manchester he had been brought into connection with pollution of both water and air, and he had done his best. He had recently received a communication from New York which seemed to throw further light on the question of the treatment of sewage in large towns—which was a development of the treatment of sewage by bacteriolosis—forcing strong draughts of air through the material through which the sewage is filtered, in such a way that immediately the strong blast of air is passed through the porous material, whatever it may be—cinders or coke—the friendly bacteria clean the whole thing out, and render it available for further treatment of sewage. If this could be established before the Royal Commission which was shortly to be appointed he believed we should get a scientific and economical way of dealing with the sewage of large towns. He could assure them that in dealing with the sewage around Manchester they had a very serious problem, in which he was deeply interested. He hoped that in time the air would in some way be made purer. Science was much at fault in dealing with smoke and the combustion of coal in our large towns, and he hoped that in the following century they might see pure air and pure water, so that they would be able to say that science had triumphed over the difficulties which enormous populations, congregated in large centres, had brought upon us more rapidly than men of science had been able to deal. (Applause.)

Dr. FARQUHARSON, M.P., in an amusing speech, replied for the House of Commons. He said that when he had had the honour of taking the chair at the Sanitary Institute not long ago he took the opportunity of saying that he had very little confidence in the House of Commons in matters of hygiene. That was quite true, for he thought both parties bad, though he thought also the party to which he was opposed was rather better than his own in this respect. But too much obstruction was put in the way of either party whenever they attempted to do anything for public hygiene. Both parties united in supporting a proposal for expenditure for the protection of our Empire; he wished it were so in matters of hygiene. What they wanted was a strong backing from outside, and he could assure them members of Parliament were very amenable to pressure from their constituents; the obstruction and opposition in the House of Commons was very discouraging to those who were trying to do a little work for the cause of sanitation, but in spite of all its defects the House of Commons was a great institution, and he did not think they had occasion to be ashamed of it. (Cheers.)

Sir E. GALSWORTHY, Chairman of the Metropolitan Asylums Board, proposed the toast of the evening "The Sanitary Institute," and said that Dr. Farquharson had said the work done by the House of Commons was great in quantity, but he gave no opinion as to its quality. Now, the House of Commons in this respect differed very greatly from the Sanitary Institute, and the House of Commons must be an inferior body. (Laughter.) For the work done by the Institute was both great in quantity and admirable in quality. It was founded in 1876 exclusively for the advancement of subjects which bear upon public health. He referred to the various developments which had taken place, to its congresses, lectures, classes, examinations all over the country, and said all branches appeared to have steadily grown, and all who desired to aid the important work of improving the public health ought to support and co-operate with it. The Metropolitan Asylums Board, which seemed to exist for the benefit of the halfpenny evening papers—(laughter)—was most anxious to co-operate with the Institute, and if its work resulted, as it should do in the diminution of suffering and disease, then perhaps the Board would be a little more economical than it is at present. He could congratulate the Institute on the splendid work it had done, and upon its sound financial condition, which spoke well for the Institute. (Applause).

The toast was enthusiastically drunk.

The CHAIRMAN, who was cordially greeted, in responding, said it was pleasing to find the Institute so well appreciated by the head of one of the most important sanitary departments in the metropolis. There were few branches of science which had made such progress during the reign of her Majesty as sanitation, and they would all agree with him that that progress had been largely due to the chemist and the physiologist, and more recently to the psychologist. Sanitarians had much to thank the progress of other sciences besides their own in these respects. But he was afraid they must all feel that sanitation had not penetrated into the nation in the way it should have done. He was Chairman of a Sanitary Committee of a County Council, and he found that numerous pollutions were going on from the houses and

small towns into the water supplies, which might have been arrested at their origin but for lack of education. (Hear, hear.) There were other matters in which he thought our sanitary services were singularly wanting, and the appreciation of the public for sanitation was equally indifferent. Large quantities of butter were being brought from the Continent made with preservatives which are dangerous to health. Steamboats were being constructed for the purpose of bringing milk from abroad to this country which would be similarly adulterated, and no efforts were being made at the ports of entry to prevent the distribution of these adulterated articles. Through the care and efforts of Dr. Corfield, and also of the Local Government Board, the quarantine had been abolished; that was a very desirable measure, but it was accompanied by a measure that all persons arriving by a suspected vessel should be carefully examined and watched for some time afterwards to see that no infection broke out amongst them. Similarly, if we admitted butter and milk free of duty, care should be taken to see that those articles were pure and did not contain matter injurious to health. He was afraid that with all their self-congratulations as to the progress of sanitation they must admit that the nation had only as yet touched the fringe of the question. So long as the higher sanitary administration of the nation remained an appendage of the Poor Law administration there could be no proper care for the health services of the country. (Hear, hear). The sanitary care of the metropolis was scattered under many Authorities, all separate from the other. In the counties and in the small towns, even in some important towns, sanitation was not appreciated. In many places Medical Officers, Public Analysts, and Sanitary Inspectors were badly paid, and nowhere have they that certain tenure of office which is necessary to ensure the fullest devotion to the services in which they are engaged. The nation still remained largely supine and somewhat ignorant of its true duties in this respect. The Victorian era had undoubtedly developed sanitation, and the improvement which it had introduced originated with pioneers like Budd, Parr, Smith, Parkes, Rawlinson, Chadwick, Richardson. But with justice he might claim that the Sanitary Institute had had an important share in the progress made during the latter years of this century. The Sanitary Institute was founded no doubt as a consequence of the recognition by Parliament in 1872 of the importance of codifying and improving the scattered laws which up to that time had regulated the sanitation of the country. The Sanitary Institute was founded for the purpose of educating the public in the requirements of this new science. It had largely fulfilled the mission which its originators set before them. They assimilated to themselves the Parkes Museum; they had developed, and now maintain it, not as a place for the display of the wares of manufacturers, but as a well-considered exhibition of what is newer and best, and the latest applications of the science of practical hygiene. As an evidence of the appreciation in which it is held, he might mention that it was visited in 1897 by 17,500 persons, and that fifty-three different institutions sent classes there to be instructed by their own professors. The Sanitary Institute held congresses in various important centres, to which the leading Sanitary Authorities throughout the country willingly came, because they were able to discuss and exchange views upon important questions which interest them. Exhibitions in connection with those congresses had been held during the last twenty years, and by the adoption of a careful and systematic method of judging exhibits they had preserved not only a continuity, but had established a uniformity in the principles upon which the awards are based. Owing to the Sanitary Institute a feeling had been created, and it was gradually spreading in the public mind that it is of the first importance that the officers who administer the sanitary laws should be thoroughly qualified for the offices they hold. The Institute originated examinations in sanitary knowledge for Sanitary Inspectors and borough surveyors, but the Surveyors' Institute, the British Architects, the Civil Engineers, had perceived how important this class of knowledge is, and those bodies now required that sanitation should be a branch of the examinations which they now require those who join them should possess. But the Sanitary Institute at present remained practically the sole examining body for Sanitary Inspectors, and it had devoted much time and labour to improving the education of those persons; 2400 certificates had now been issued for competency and qualification to hold the offices of Sanitary Inspector. Through much difficulty and through many troubles they had attained to their present position; the Institute had not more than 2000 members; it had an invested capital of nearly £11,000, and an income in excess of expenditure, and they devoted that income entirely to extending their influence and usefulness. (Cheers.) The past principles of the Institute had been to devote their funds entirely to the maintenance of their museum and library, and the organisation of lectures, not only for the public, but chiefly for the education of Sanitary Inspectors, for whom they had provided special lectures in various parts of the country. They now contemplated establishing classes to supersede those lectures because it was believed classes would be more effectual means of education than the lectures. Further, the lease upon which they held their premises had not many years to run, and they were now considering how to extend their usefulness either by an addition to their present buildings, or by the acquisition of a new site. They had progressed steadily in the past, because they had had before them a single-minded desire to convey to the nation a due appreciation of the value of sanitation, and to assist its progress; and so long as they continued to administer the Sanitary Institute on the same lines he did not think they need have any fear as to its future progress in usefulness and in success. (Loud cheers.)

The proceedings then terminated.

ARRANGEMENTS FOR THE BIRMINGHAM CONGRESS.

The proceedings of the Congress to be held in Birmingham next September in connection with the Sanitary Institute were foreshadowed on Thursday, the 24th ult., at a preliminary meeting at the Council House, presided over by the Lord Mayor (Councillor C. G. Beale). The Congress will meet from September 27th to October 1st, the

formal reception of the members on the first day being followed by a public luncheon and the delivery of the inaugural address by the President, Sir Joseph Fayrer, Bart. Conferences will be held on various topics on the Wednesday, and a conversazione and reception will take place in the evening. Thursday and Friday will be devoted to sectional meetings, at which important papers will be read and discussion invited on sanitary science, engineering, &c. There will, of course, be the usual excursions and visits to places of interest in the neighbourhood, Saturday, the last day of the Congress, being occupied entirely in this way. The feature, however, that will perhaps appeal most to the general public will be the exhibition of sanitary appliances, &c., that will be arranged in Bingley Hall. The exhibition in Leeds last year was a great success, and beat all previous records, but it is anticipated that the one to be opened in Birmingham will be far larger and much more interesting and representative than any of its predecessors.

LOOKING AHEAD: A PEEP INTO TWENTIETH CENTURY SANITATION.

By M. Ingram, Manchester.

(*Continued from page* 312.)

The good existing sewers remain substantially as they were made under the old system, but nothing is allowed to enter into them, only that which falls from the clouds; but if from any class of manufacturers' waste, it is made equal in purity to rainwater *when it enters the sewers*. This is a condition precedent before it is allowed to enter such sewers, and any infringement of the *law* in this respect is punished by fine or imprisonment, and we now find our rivers, in which Waltonians delight to ply their hook and line, restored to their ancient purity.

Now let us see how the system works out in actual practice. For this purpose let us take a typical place, Manchester and Salford, for instance, where there are, we believe, six main arterial railways radiating from their centres, each one of which has placed along its course an iron outfall main sewer pipe of comparatively small dimensions, the largest of which is but 18in. in diameter, whilst others are much less. This is managed by reason of mapping the city and borough into small drainage areas or districts, and every district has its own main into which every house in such district is connected. The course of this main is always in the direction of the principal arterial tubing, which, as before mentioned, takes the course and direction of the various arterial railways into which all the pipes from all the various districts ultimately join; in short, very much as the present water supply pipes, with this difference, the flow is *from* the house, and not to it, as in the latter case. The "flow" or motion of the materials inside the pipes is brisk, if not very rapid, and is always towards the open country. The sewage consists of a comparatively small quantity of water, sufficient only to carry the solid matter forward, which solid or other putrescible matter having previously by a simple manner been rendered innocuous by a chemical preparation at the moment it is discharged into the drain tube, and at all suitable points of the route, but away from inhabited houses. The main pipe is tapped, as it were, and its contents used upon the land, the fertilising qualities of which make it much sought after by farmers, who have at disposal a manure ready at hand at any hour to apply to the soil, when and how experience has taught them to be most beneficial.

Be it observed that a considerable impetus could not be maintained in the pipes, either main or branch, without some motive power being employed. This, however, is not considerable, by reason of the gradients being so easy; the power needed is comparatively small and inexpensive, for at suitable positions pumping stations are erected and atmospheric air is forced into the pipes, forming an air current in the direction desired, and thereby accelerating the flow of sewage, preventing any stoppage, aërating the contents of pipes, and making a leakage of sewer air *into* the house an impossibility, and also making the sewage harmless to handle at its ultimate point of disposal upon the land.

The ventilating pipes from the drains as formerly employed, are things of the past; the unsightly pipes attached to the house, as well as the unsavoury grids in the street, are tolerated no longer by an intelligent people, who make their sanitary surroundings their first duty, and impose the same obligation upon those sent to represent them in the Imperial or Municipal Councils—indeed, a jerry builder or a "bodging" plumber would stand no chance of election by so intelligent and so enlightened an electorate.

We have seen what progress has been made in the collection and disposal of the wastes of life in a few years, by reason of the removal of restrictions and vexatious and harassing legislation, and by means of public opinion, making public health the watchword and the battle-cry of both political parties—a contest in which all electors make a point in taking an active and an intelligent part.

Let us take a look inside a domestic dwelling, and notice some of the changes made both in form and principle in some of the sanitary appliances therein, the most noticeable of which is the water-closet, which, by a process of evolution, has changed from the large porcelain basin to a small metallic receptacle, in shape somewhat similar to a double ellipse, with its longest dimension about 12in., whilst its shortest or transverse width is but from 3in. to 4in. It has a seat suitably poised, and supported in such a manner that when in use the deposit is made in that portion of the receptacle, which is prepared specially for it by its peculiar formation of its bottom portion. On rising from the seat a suitable metallic disc or lid falls into a place prepared for it, and covers the orifice of the basin, provision being made by the peculiar construction of both basin and lid to make it water-proof, and also to withstand the water pressure to which it is later on subjected, in order that the contents may be forced right away, far into the drains previously referred to. The water supply is on the high-pressure principle, and by this means it is found that about one quart of water is quite sufficient, not only to thoroughly cleanse and flush the basin, but also to make the joint between the disc and the basin. At the completion of this very successful flushing operation, a small charge of a chemical compound is then ejected into a basin from a suitable receptacle by means of compressed air, which chemi-

cal mixture is deposited inside the basin ready to receive and amalgamate with its next contents. This chemical preparation is a cheap by-product, and is supplied gratuitously by the Municipal Authorities. The mechanical motion required to accomplish this last operation is obtained by the act of moving from the slip in front of the water-closet basin. Amongst the other novelties of this closet it has no trap, and the soil pipe is but 2in. in diameter, and is made of strong iron and porcelain enamelled inside. Bearing in mind that some considerable pressure is maintained in the public drains, a kind of back-pressure valve is fixed in a suitable position, which thus cuts off all direct communication therewith.

An installation of compressed atmospheric air is now considered a public necessity, hence no domestic residence is deemed complete without it, and no intelligent householder would occupy a house without this provision, the beneficial uses of which are so advantageous in giving motion to the atmosphere in sick and other rooms, as well as providing the means for ventilating and warming the whole house whenever required.

The lavatory and bath have undergone but little improvement; they are, however, in more extended use than formerly, and every house, however small, is now provided with these indispensable sanitary appliances. Indeed, it is considered public policy to encourage the practice of frequent ablutions, therefore every facility is afforded by the provision of a gratuitous supply of hot water for this purpose, the waste from which is taken into the storm outfall drains.

Waste water from the scullery and slop sinks is taken into the arterial drains in a manner somewhat similar to the connections from water-closet apparatus. The ruling principle guiding all these sanitary methods is to prevent stagnation in any portion of a household, and all removable objectionable matter is removed the moment it is desired. This principle also applies to the removal of domestic refuse. There is no accumulation awaiting the arrival of a collecting van, or the crude methods of the same, nor transit through the streets polluting the atmosphere by the floating particles of its contents along its entire course to its destination. The principle now adopted is to place the refuse within a suitable iron receptacle, porcelain enamelled inside, and upon securing the cover, it is "whisked" instantly away in pipes provided for this purpose by means of compressed air, to depôts suitably situated, when it is ejected with some force right into a crematory furnace, the heat thus obtained being used to supply power for compressing air, providing hot water for domestic supply, lighting, and other industrial purposes.

In some districts where it is either inconvenient or impracticable to connect the sewage pipes to the arterial drains, both the liquid and the solid refuse is converted into gas for lighting or heating purposes without personal manipulation of any human being whatever, but by the same mechanical methods already named.

It has been found that batteries of muffle furnaces electrically heated are more efficient and less costly than the old retorts for converting this combined wet and dry refuse into gas. At the same time the by-products are more useful and more valuable.

INQUIRY INTO THE CONSEQUENCES OF THE DEPOSITING OF TOWN REFUSE.

K. KRATZ, Ph. Doc. of the Hyg. Inst. of the University of Giessen (Z.f.H., u. Inf. B. xxvi. H. 2), in view of the fact that through the expansion of towns, sites selected as shoots for the deposit of dust, slops, and refuse of all kinds, frequently become surrounded by houses, and are sometimes disused and built over, undertook a minute investigation of the condition of the site of that at Giessen, and the pollution of the soil, with the influence it might exert on the health of the neighbourhood, and of the houses that might later be erected thereon. The procedure he followed was that adopted by Proskauer at Berlin, and deserves attention for its exhaustive character. He began by making twenty nearly equidistant borings, from 3 to 4½ metres in depth, to the natural soil beneath, taking samples at each metre downwards. One hundred grammes from each sample dried at a temperature of 100 deg. Cent. were diffused in one litre of distilled water, and the filtrate examined as for potable waters; the soil itself was roughly examined for organic and inorganic matter, water, and iron; and the ground air pumped from different depths for CO^2 and H_2S, &c.; the temperature at each metre from the surface was taken, and the influence of the rise and fall of the contiguous river Lahn on the movement of the ground-water determined. Lastly, the bacteriology of the natural and of the "made" soil, both crude and sifted, was thoroughly studied at each metre or half-metre in depth, including the natural subsoil underlying the refuse, which the borings frequently penetrated to a depth of one to three metres. The activity of the nitrifying and denitrifying bacteria, which cannot be cultivated like others, was estimated by the rapidity with which they effected the disappearance of ammonia, nitrates, and nitrous acid from solutions of ammonium nitrate and sulphate. The only pathogenic microbe sought for was that of tetanus. Twenty mice were inoculated with watery extracts from as many samples taken from ten of the borings, including those in the natural meadow. Of these twelve died tetanic, the soil from the meadow and some samples of the natural subsoil beneath the made earth proving inert, but all those of the latter which were thus tested being infective. The analyses of the water from the infusions give a good idea of the extreme pollution of the made soil, and frequently of the subsoil, and the danger to health not only of the persons occupying houses built on such sites, but also of those who should drink the water of wells sunk in the immediate neighbourhood.

POPLAR.—On Wednesday afternoon, the 23rd ult., the dust destructor erected by the Poplar District Board of Works on land in Glaucus-street, Bromley, at a cost of £11,000, was opened by Mr. Mark Dalton, J.P., Chairman of the District Board of Works, in the presence of a large number of representatives of the District Board. The site was procured at a cost of £3500. The destructor, which contains fourteen cells, is calculated to destroy about 130 tons of refuse per diem, and the shaft is 150ft. from the surface of the ground.

Sanitary Inspectors' Associations.

WESTERN.

A MEETING of the Western Branch of the Sanitary Inspectors' Association was held at Gloucester on Saturday last, and was attended by a large number of delegates. A reception was held by the City High Sheriff (Mr. A. Woodward) and Mr. A. King (Chairman of the Sanitary Committee of the Corporation) at the Guildhall, when the Association was heartily welcomed by Mr. King and the City Sheriff on behalf of the city; and Mr. Macmahon, Chairman of the Western Branch, suitably acknowledged the greeting. At a general meeting of the members held in the Bow Committee Room, the hon. secretary (Mr. T. J. Moss Flower) and Mr. Kirley (Bristol) announced that they had written to the members of the Bristol district asking them to support the Bill to be introduced into Parliament for securing tenure of office and superannuation for Sanitary Inspectors. They had pointed out that Poor Law officers were already protected in this way; but the Sanitary Inspector, who daily carried his life in his hands, was not. Mr. Lewis Fry, M.P., and Colonel Sir E. Hill, M.P., had promised, the first-named to support, and the second to favourably consider the matter; but the Right Hon. Sir M. E. Hicks-Beach replied that it would be contrary to rule for him, as a member of the Government, to allow his name to be placed on a public Bill which was not introduced by the Government.

A public meeting was subsequently held in the Assembly-room of the Guildhall, Councillor King presiding, when papers were read by Mr. R. Read (Gloucester), on "Notes on Sewerage, Drainage, and the Water Supply of Gloucester;" by Mr. T. G. Dee, Westminster (Chairman of the Association), on "Tenure of Office;" and by Mr. W. H. Grigg, Fulham (Vice-Chairman of the Association), on "Some Reminiscences of Our Belgian Visit." Mr. F. W. Waller and Mr. Medland described various buildings to be carried out by the Corporation at Gloucester, and the members afterwards dined together at Garrett's Restaurant; Mr. King again presiding. A number of the delegates subsequently drove round to inspect places of interest in the city.

NORTH-WESTERN AND MIDLAND.

A MEETING of this branch of the Sanitary Inspectors' Association was held at Stafford on Saturday last. Prior to the meeting the members visited the Royal Brine Baths, the County Buildings, and the Corporation Sanitary Depôt and Sewage Works, they being conducted by Mr. W. Blackshaw, the Borough Surveyor, and Mr. J. Evans, the Borough Sanitary Inspector. Dr. G. Reid (the County Medical Officer) presided over the meeting, which was held at the Shire Hall, and there were also present Mr. W. Urquhart (Crewe), chairman of the Council, Mr. H. H. Spears (hon. secretary, Waterloo), and representatives from Birmingham, Uttoxeter, Stafford, Seisdon, Hanley, Smallthorne, Audley, Liverpool, and Nottingham.

A memorandum from the Society of Public Analysts respecting the proposed amendment of the Sale of Food and Drugs Act was referred to the Council for consideration and report. The main points in the memorandum were that a court of reference should be constituted, and that the recommendations of the Select Committee which had sat on the question should be incorporated. The Secretary explained the chief provisions of the Sanitary Inspectors' Appointment and Superannuation Bill which was shortly to be brought before Parliament. The promoters of the Bill seek to obtain greater fixity of tenure for Sanitary Inspectors, it being pointed out that at the present time Inspectors were placed at a disadvantage in that they might have to serve notices to abate nuisances on persons who occupied positions on the Boards invested with the power of appointment and dismissal. The Bill laid it down that the dismissal of Inspectors should rest with the Local Government Board.

Mr. LOWRY (Seisdon) proposed that the Bill should be approved, and the motion was seconded by Mr. WATERS (West Bromwich), and carried unanimously, and it was left to the Council to organise a movement in favour of the Bill among the members of Parliament.

The SECRETARY presented a report on the proposed amendment of the rules of the Association so as to facilitate the creation of district centres, and it was decided, on the motion of Mr. LOWRY, seconded by Mr. HIGGINSON (Audley), that a Midland centre shall be established, a provisional committee, with Mr. Carter (Birmingham) and Mr. Kent (Hanley) as joint secretaries, being formed to make the necessary arrangements for giving effect to the motion.

Mr. A. KENT (Hanley) read a paper on "The Protection of Water Supplies." He said that there was no part of the work of a Sanitary Inspector which exceeded in importance that of the water supply, as the health of a whole community depended upon a pure supply. Public bodies, especially in rural districts, had to contend with great difficulties, the procedure necessary to get a good supply of water being cumbersome, and he contended that more extensive powers were necessary in order that the health of the people may be better safeguarded. Power should be given to Local Authorities and their officers to enter waterworks from which the public were supplied in order to take samples for analysis.

The CHAIRMAN said that the rough-and-ready test suggested by Mr. Kent would not be of any value, as though it might show that the water was bad it would not show that it was good. Mr. Kent was thanked for his paper, and the meeting ended.

MAIDSTONE. — During the typhoid epidemic eighty-four nurses and attendants allowed themselves to be vaccinated with the lymph, and of these not one contracted the disease. On the other hand, 120 refused to be vaccinated, and of these sixteen were attacked.

QUEENSBURY. — A Local Government Board inquiry has been held into the application of the Urban District Council for powers to borrow £1500 to provide a water supply scheme for the mountain portion of the district. The scheme has been rendered necessary owing to the fact that the present reservoir is on a level below this portion of the district, which has a population of about 600.

Institute of Sanitary Engineers

THE SANITARY ADMINISTRATION OF BELFAST.

(*Continued from page* 316.)

During the cholera alarm of several years ago the Port Sanitary Officer carried out the same system upon all vessels and their crews arriving from suspected ports. To allay any reluctance on the part of the sailors, the officer always underwent this fumigation with them, finding no ill result from it.

One of the most important questions that can claim the attention of a Health Department is the disposal of the town refuse. It has been previously stated that the Belfast Corporation periodically cleanses all ashpits at the expense of the rates. The disposal of the material is a problem of no small difficulty, varying as it does so largely in composition. So long as a large proportion consisted of organic matter, it could be collected at the Corporation manure yard and sold to farmers at a price sufficient to materially reduce the cost of collection. But as the contents of the pits became in a larger proportion ordinary ashes, and in view of the outcry against the existence of such a manure yard within the City boundaries, this method of disposal has become, at the same time, more difficult, as well as less profitable. It is not surprising that the Corporation manure yard has therefore shrunk in size by at least one-half during the last four or five years. The question of a refuse destructor has been at intervals before the Council, and its adoption cannot now be much longer delayed. The refuse to be disposed of by a Corporation may be divided in the main into four different classes. First, the ordinary road scrapings. The organic matter in this is seldom of sufficient amount to render it unsuitable for ordinary filling-up purposes, and would be still less so if the Corporation extended their excellent practice, at present confined to two or three leading thoroughfares, of gathering up promptly all the manure that falls, and which among other advantages must tend greatly to mitigate the obnoxious character of street dust. The second article to be disposed of is the ashpit contents, and in connection with this, and which would render it more easily dealt with in a destructor, should be the compulsory covering over, as previously suggested, of every ash pit. The third class is the stable and cow-house manure. Very little of this has to be dealt with by the Corporation, as the owners find a ready market for it. The fourth is a miscellaneous class, and consists of all sorts of rubbish from business places, houses pulled down, dead animals, paper, straw, &c. The filling up of waste ground has already been referred to. During the past year permission has been given by the Public Health Department for rubbish to be deposited upon several pieces of waste ground, mostly upon the river bank, and upon the understanding that no building should be erected upon the ground for seven years. The Corporation have availed themselves of their own leave, and made large deposits themselves upon these sites. Judging from the composition of one of these, seven years is by no means long enough to prohibit building upon. It is, in fact, a large spoil bank, 150 yards long by 50 yards wide and 10ft. in average depth, and the innocuous portion of its contents appears to be decidedly in the minority. I am inclined to think that this, as well as some other lapses from strict sanitary propriety, have been perpetrated to a great extent without the knowledge, and with merely the nominal sanction of the higher Authorities. Permission is given to fill up certain spots under what appears to be reasonable safeguards, and the door once opened, advantage is taken by all sorts of persons to get rid of all sorts of objectionable matter, and even the city scavengers, doubtless to save themselves a little trouble, become the chief offenders. The existence of a destructor would take away one excuse; the presence of a policeman with eyes and a very little common sense, would prevent much. Or, were this not feasible, a small charge might be made, enough in part at least to pay for a watchman having power to turn back or otherwise deal with anything that was obviously unfitted for deposit.

The notification of, and the methods of dealing with, zymotic disease, have already been touched upon, and it might perhaps have seemed more logical to have discussed its prevention at the same time. The topics are, however, sufficiently distinct as not to render it out of place to treat them separately. In this place we may confine ourselves, to two or three of the more important, or at least those which appear with the most regularity and persistence, because some, like scarlet fever and measles, however serious, depend so much upon outside influences, and fluctuate so greatly, that we may for the present put the discussion of them aside.

The three which occupy a place of more regular persistence, and upon which a Public Health Department is expected to have a definite policy, and also as to which Belfast holds a rather unenviable prominence, are typhoid or enteric fever, diphtheria, and phthisis. Especially in the first and last of these our death-rate is abnormally high. With regard to typhoid, Sanitary Authorities would be in a much surer position if they could always put their finger upon the cause. No doubt they can, and have done this in such cases as those recent epidemics at Maidstone and Lynn, and as in numerous others traceable to particular contaminated milk supplies. But in Belfast (and in Dublin also) there seems to be a regular sporadic existence of this disease, varying but little from year to year, and so distributed as to point to no single source for the infection. For many years the popular idea, both in the medical profession and the public, was that in sewer air or sewer "gas" we were to look for the chief cause of this disease, and this has gone to such an extent that there has been a perfect craze upon the subject of drains. The plumber and the sanitary engineer have reaped a rich harvest from this state of things, and whenever a case of typhoid has occurred the doctor has naturally asked after the drains, and if a leaky joint has been discovered anywhere in the vicinity of the house, it has been immediately set down as the originating cause. Recent investigations would seem to show, however, that we may have been at least somewhat premature in our conclusions.

The researches made by Mr. Parry Laws at the instance of the London County Council into the micro-organisms to be found in sewer air may give the sewer-gas panic-mongers a moment's pause. According to Mr. Laws the number of pathogenic organisms in the air of sewers is no greater, and sometimes even less, than in the air outside. More striking still is the fact that those which are found are not such as inhabit sewage, but have mostly been introduced from the air outside, and are of the same class as are found elsewhere. Nevertheless, while typhoid is to be found in every district of Belfast, it is somewhat more prevalent, in general, in the hillside parts of the town, and those in which it might be presumed there was a greater chance of the gases rising through leaks of the drains or forcing defective traps. Sir Charles Cameron, the Medical Officer of Health for the city of Dublin, and whose name carries with it no little authority, has started the suggestion that "underground air" may be one of the chief vehicles for conveying the typhoid bacillus or its germs. This theory does not seem to present quite so much difficulty as the case against sewer gas does, and tends partly to explain some of the caprices and fluctuations of the infection. It is not surprising, when one comes to think of it, that the latter should not contain many sewage microbes; so long as the sewers are freely running and their sides remain moist they are not in a condition to communicate them to the air. In soil, on the other hand, which has become saturated with the percolations from defective drains, or pervious ash-pits, and in which there are alternations between moisture and dryness, the soil when continuously moist may give out few or no germs into the air, but when dried the germs would be freely given forth, and either be sucked upwards by the warmer air of the houses, or else forced upwards by the advancing moisture when a wet season intervenes. This in part would explain the frequent increase of typhoid after the commencement of the autumn rains. It might also explain what at first sight appears the anomalous fact, that in the lower and oldest parts of the town, where the drains were in general not only defective, but constantly dammed back by the rising tide, and the subsoil presumably fully saturated with sewage matter, there should actually be less typhoid than in the upper districts, for the most part built and drained within the past twenty-five years. The street drains in these having a rapid fall may frequently have their sides comparatively dry, and be much more likely to communicate germs into the air; and the subsoil, though relatively not perhaps as foul as in the lower levels of the town, would nevertheless be much more exposed to seasonal fluctuations of moisture and dryness. Nothing has here been said as to water-borne sources of infection, because there is no clear evidence that this has had much to do with the disease in Belfast. The water supply has of late years been ample. It generally amounts to thirty-five gallons per day for each person, the gathering ground is almost entirely moorland, and the water has been for some years all filtered. When the new supply from the Mourne Mountains, in the south of the County Down, comes into use, as it will before long, the Belfast water supply will equal, if not surpass, that of any city in the United Kingdom.

Notwithstanding the great progress made in recent years in public sanitation, the continued persistence of diphtheria has taxed the energies, and has not been to the credit of sanitary reformers. It is to be feared that the spread of popular education, now everywhere made compulsory, is to be held partly responsible for this. The crowding together of so many children of the poorer classes must greatly facilitate the spread of infection, especially as the ignorance or apathy of their parents renders them less watchful of the beginnings of illness than those of the more educated classes generally are. The National Schools are, of course, subject to regulations as to lighting, ventilation, and overcrowding, though whether these are yet sufficient may perhaps be doubted, and in some respects Medical Officers of Health would probably like to see them extended. There must be a very large number of private schools frequented by children of the middle class which practically are under no supervision whatever. In these young and susceptible children are, it is to be feared, often packed far too closely, and with no sufficient intervals for exercise, or for the changing the air, into rooms in private dwelling-houses by no means adapted for the purposes of a school. Under some clause or another, or under the general scope, of the Public Health Act, the Corporation ought to find power to make rules to govern such cases. In all cases, public and private, it can hardly be doubted that more frequent recess intervals, however short, would be of great help in promoting the health of the scholars, and, for that matter, of the teachers also. Musical drill, while the windows were open, would also provide exercise and ventilation, without risk of taking cold.

But the great scourge of all is phthisis. It is almost a pity that this phrase has not been superseded by "tuberculosis," as being more comprehensive, because the disease is by no means confined to the lungs, and part at least of its mortality is due to other parts of the body, and in this respect a stricter definition might help us to fuller measures of precaution.

Some of these have been considered under the subject of cow-houses. It has been also stated that this is peculiarly a disease of *houses*, and more than that it is also peculiarly a disease of the *poor*. From what we know of it we need hardly be surprised at this. The infection—for in the truest sense of the word it is infection—comes mainly from the sputa of those who suffer from it. When this is carelessly, or at least ignorantly distributed over the floor, it is bound, when dried and swept up or otherwise disturbed, to constitute an atmosphere laden with disease germs. It only remains then to provide lungs or throat affected by an acute state of weather, or a debilitated system, to furnish a suitable cultivation ground for the disease. The question how to meet it is a problem of no small difficulty. One thing that may help us is this, that the tubercle bacillus dies speedily under the influence of direct sunlight, and doubtless also free oxygen is unfavourable to it.

(*To be continued.*)

FOLESHILL.—The Rural District Council has received a letter from the Local Government Board expressing regret that the Council had been obliged to put up a temporary iron hospital to cope with the outbreak of typhoid fever, and urging them to endeavour to obtain a permanent hospital.

General News.

YARMOUTH.—The sanction to the loan of £12,000 for the destructor has been received.

BRIGHTON.—The Local Government Board has sanctioned a loan of £2480 for twenty years on account of the refuse destructor.

BOLTON-LE-SANDS.—Plans for sewer extension have been approved by the Parish Council. The cost of the scheme is about £500.

LEAMINGTON.—The Town Council has borrowed £5500 for carrying out the work in connection with the supplemental borough water supply at Lillington.

STOURBRIDGE AND HALES OWEN.—Arrangements are to be made for the borrowing of £10,000 for the erection and equipment of the hospital and acquisition of the Hagley Green site.

LLANELLY.—The estimated cost of the proposed Llwynhendy water supply is £1700. The Rural District Council has now resolved that Furnace and Sandy be included, and that the plans as drawn out be accepted.

NORTHAMPTON. — The Town Council has decided to acquire a destructor for the disposal of the town refuse, and to provide a steam disinfector, a weighing machine, steelyard, and fittings on Wood-hill, and to construct an underground public convenience.

INVERURIE.—A meeting of the special committee appointed at the stated meeting of commissioners was held recently for the purpose of considering as to the desirability of having a public slaughter-house erected within the burgh. After full consideration, it was agreed to hold a conference with the butchers to consider the question.

TUNBRIDGE WELLS.—The Borough Surveyor (Mr. E. Mellor) has just submitted to the Waterworks Committee of the Town Council a scheme for new filtration works at Pembury, where the reservoirs are situate. The estimated cost of the scheme will be about £20,000, and before the next meeting of the Council, Mr. Strachan, engineer, is to be consulted.

LANGTON MATRAVERS.—As a result of the Local Government Board inquiry which took place with regard to the contemplated borrowing of £1000 for the purpose of a water supply, the Board has intimated that it does not consider the scheme satisfactory, and desires to be furnished with a geological report. The District Council has now agreed that the report required be obtained and forwarded.

WITHINGTON.—The Local Government Board inquiry into the application of the Urban District Council for power to borrow a sum of £5500 for the purchase of land on which to erect an infectious diseases hospital on the Baguley Lodge Estate was resumed on Thursday, the 24th ult. The burden of the case for the opposition was that the site in question was unsuitable for drainage purposes, and that the surrounding property would deteriorate in value if the hospital were erected.

GRANTHAM.—The Grantham Waterworks Company propose to considerably increase the present plant at their pumping station.

BRAMLEY.—A loan of £1250 has been obtained by the Guardians from the Leeds City Council for the furnishing of the new hospital.

ROWLEY REGIS.—It was reported at a recent District Council meeting that the Staffordshire County Council had decided to take steps to adopt a scheme to make joint hospital districts, and under the circumstances it was decided not to entertain a proposal for the Oldbury District Council to remove small-pox patients to the Tividale district.

BLYTH.—At a meeting of the joint Councils of South Blyth and Cowpen, held last week, it was decided to obtain tenders for building a temporary hospital, suitable for small-pox cases, to accommodate about thirty patients, upon the ground offered by the Port Sanitary Authority, the cost of the building and furnishing to be defrayed by the two Councils.

MORECAMBE.—At a special meeting of the Urban District Council tenders for refuse destructors were produced and examined, but their further consideration was adjourned. A Committee, together with the Surveyor and Electrical Engineer, are to proceed to Stretford, Manchester, and Bury, or Birkenhead, to inspect the refuse destructors in use at those places.

LONDON.—The first of a course of lectures on public health was given on Tuesday afternoon, the 22nd ult., in the Lecture-room of the National Health Society, Berners-street, W. The lecturer, Miss Alice Ravenhill, spoke of the meaning of public health and the necessity of laws to guard it. She explained the scheme of English Local Government, with special reference to the laws dealing with infectious diseases, vaccination, &c.

BIRMINGHAM.—The work of cleansing the courts in the city is proceeding very satisfactorily, and at the present rate of progress it will not be very long before we are without a single dirty court in Birmingham. At no other time in the history of court life has it been possible to say as much; but the power possessed by the Corporation having been once invoked, the people are not likely to be allowed to relapse into the state of filth which, in too many cases, has been a disgrace to modern civilisation.

DOUGLAS.—The Water Committee of the Town Council has under private consideration the report of Mr. George H. Hill, Water Engineer, just received, on a scheme of increased water supply for the town of Douglas. Kerrowdhoo, the last reservoir of the company, with a storage capacity for about 25,000,000 gallons, was completed about five years ago. Mr. Daniel Cregeen, the Manx engineer, at that time advised a larger scheme at Ingebreck. Mr. Hill's report is for a new reservoir in West Baldwin at a point lower on the river than Ingebreck, having an area of about twenty-five acres, and to contain 300,000,000 gallons. The reservoir must be this size if compensation water is to be provided for mill works in Douglas river, and the cost will be £50,000, but if compensation is given in money instead of water, a reservoir with a capacity for 180,000,000 gallons will be sufficient, and will cost about £8000 less.

Personal.

MR. W. HULME has been appointed Vaccination Officer for the union of Worcester.

MR. FRED. RAYNER has been appointed Surveyor for the urban district of Newhaven.

DR. MATTHEWS has been re-elected Medical Officer for the rural district of Machynlleth.

MR. J. D. LLOYD has been appointed Medical Officer of Health for the rural district of Chirk.

MR. HOBBLING, of Hartland, has been elected Medical Officer for the rural district of Bideford.

MR. R. CLEMENTS has been appointed Surveyor and Inspector for the urban district of Barkisland.

MR. R. W. J. EWART has been appointed Medical Officer of Health for the urban district of Masham.

MR. H. B. WOODCOCK has been appointed Assistant Medical Officer of the Salford union infirmary.

MR. G. WIGNALL has been reappointed Assistant Surveyor for Loughborough, at a salary of £50 per annum.

MR. JASON C. WILSON has been appointed Sanitary Inspector to the Vestry of St. Mary, Newington.

MR. JOHN E. H. DE KEY has been appointed Inspector of Nuisances for the urban district of Wellingborough.

DR. PRATT, Appledore, has been appointed Medical Officer for Northam in succession to Dr. Rouse, deceased.

DR. PAYNE has been reappointed Medical Officer for the parish of Farcet, under the Peterborough Board of Guardians.

MR. JOHN WARD, of Wratislaw, deputy city engineer and surveyor of Sheffield, has been appointed Borough Surveyor for Derby.

MR. D. H. W. POWELL, the Surveyor of the Kingswood District Council, has resigned owing to his having obtained an appointment in the western district of Wadney, Oxfordshire.

MR. GEORGE GREEN, recently Assistant Surveyor to the Islington Vestry, has been appointed Surveyor to the parish of St. Martin-in-the-Fields, in succession to Mr. Charles Mason, who resigned his appointment.

DR. THOMAS OLIVER, M.D., F.R.C.P. (Lond.), of Newcastle-upon-Tyne, has been appointed by the Home Secretary to represent the Home-office at the International Congress on Hygiene to be held in Madrid in April next.

Lighting.

PLANS, &c., are being prepared for extensions and improvements at the gasworks in Dundee. The additions proposed to be made to the Convalescent Home are estimated to cost close on £4000. The Harbour Trustees have agreed to secure a new dredger, and to effect various repairs and improvements to their existing dredging plant at a total cost of £9290.

LEITH Corporation has received the sanction of the Dean of Guild Court to erect electric lighting station buildings off Great Junction-street.

THE Dudley Town Council has decided to adopt the recommendations of a Committee as to the tramway and electric lighting schemes for the town.

THE Hammersmith Vestry has sanctioned the application of the Electric Lighting Committee for a loan of £31,000 to extend the electric lighting works.

THE City Council of Exeter has decided to apply to the Local Government Board for permission to borrow £7000 for additional plant and cables for electric lighting purposes.

BARMOUTH is shortly to enjoy the blessing of electric light, and a movement is on foot to acquire the old reservoir at Ceilwart whereon to erect the necessary plant for the generating of electricity.

THE Gas Consumers' Protection League has decided to raise a fund for the purpose of carrying on a vigorous agitation against the proposed increase of the price of gas by the Gas Light and Coke Company.

FOLLOWING up the action of the Vestry, the Shoreditch Board of Guardians has written to the Gas Light and Coke Company strongly protesting against the rise in the price of gas, which has excited so much indignation throughout this part of London. Strange to say, the Bethnal Green Board has taken no action in the matter.

WE understand that an inquiry is being made by a Committee appointed by the Home Secretary into the extent to which water gas and other gases containing a large proportion of carbon monoxide are being manufactured and used for heating, lighting, and other purposes, and the dangers which may attend such manufacture and use.

AS the Windsor Electric Light Company is desirous of tendering for the street lighting, with the permission of the Corporation, as an experiment it installed one of its lights last week at the brow of Thames-street, on the Castle side, and just opposite the Great Western Railway Station approach. The light, which is of 1500-candle power, is fixed on an iron column about twice the size of an ordinary lamp-post.

AT a recent meeting of the Lighting Sub-Committee of the Cleaning and Lighting Committee of Edinburgh Town Council it was resolved to allow the Gas Commissioners to experiment with incandescent light in Middle Meadow-walk, Drummond-street, Melville-street, Queen-street, and Lutton-Place at their own expense. The Committee also agreed to recommend that electric lighting be introduced at Calton-road, Corstorphine-road, Inverleith-row, and London-road.

NOTWITHSTANDING the growing use of the electric light, gas is year by year growing in demand. Turning back to the year 1890, it is found that the total amount of gas made by the authorised gas undertakings of the United Kingdom was 103,011,038,299 cubic feet, as compared with 127,041,603,412 cubic feet in the year 1896, which is the latest date to which the recently issued Board of Trade returns apply. That shows an increased output of 24,030,565,113 cubic feet in the six years.

A PRIVATE meeting of the Perth Gas Commission was held recently to consider a minute and recommendation of the Gasworks Committee as to the engineer to be employed on the plans and cost of the new gasworks. The Committee, it is understood, recommended the appointment of Mr. Foulis, gas engineer, Glasgow. His appointment was agreed to, and the plans of the new works and everything relative thereto will be forwarded to him for consideration as to whether they ought to be modified or whether increased borrowing powers shall be taken.

Sewerage Schemes.

[To MUNICIPAL ENGINEERS AND SURVEYORS.—The Editor will be pleased to receive items for publication relating to sewerage schemes projected or inaugurated, together with explanatory diagrams or photographs. The former should be drawn and lettered in black ink.]

TENDERS are to be invited by the Biggleswade Council for the Arlesey sewerage scheme.

THE District Council of Benfieldside has decided upon the enlargement of the settling tanks and new filtering beds.

IT appears that claims of East and West Ayton for a drainage scheme are coming under the notice of the Scarborough Council.

THE Surveyor to the Higham Ferrars Council is preparing an amended scheme for the proposed sewerage and sewage disposal works.

THE Lee District Board of Works has decided to memorialise the London County Council as to the defective sewerage in the lower part of Charlton.

THE Adlington (Lancashire) Urban District Council has decided to make certain extensions of its sewage purification works. Mr. McCallum, of Manchester, is the engineer.

A LOCAL Government Board inquiry has been held at Swanage concerning the application of the Urban District Council to borrow a sum of £8500 for sewerage purposes. Mr. Francis Newman, the engineer, laid the plans before the Inspector and explained their details.

AT a special meeting of the West Hartlepool Corporation the drainage scheme propounded by the Borough Engineer was adopted. The scheme is to be carried out sectionally, and involves an outlay of £60,000 to £100,000.

THE recent application to the Local Government Board to sanction a scheme of drainage and sewage disposal has caused considerable interest in Keynsham, and a meeting of owners and occupiers was to be held last Monday to consider the matter of expense.

A LOCAL Government Board inquiry was held at Croydon last week into the application of the Council to borrow several sums, including £7000 for Norbury drainage; £550 for outfall sewer, South Norwood; and £500 for additional settling tank, South Norwood Farm.

THE Urban District Council of Ardsley has instructed Mr. T. S. McCullum, of Manchester, to prepare drawings, &c., for dealing with the sewage of the Measboro, Dyke and Hoyle Mill districts. The main works of the Council have already been completed by the same engineer.

THE Stactforth Rural District Council recently considered a report relative to the alleged pollution of the Tees at Stactforth; the Committee stated that there was no pollution of the river by sewage. It was decided to defer any action until the Commission appointed by the Government has reported on sewage disposal.

AT the last meeting of the Tutbury Urban District Council, Mr. W. E. Willcox, C.E., attended and read his report on the disposal of Branstone sewage. He favoured a comprehensive scheme, which he estimated to cost £2440. It was resolved that the plans be referred to the Parish Council, and that Mr. Willcox attend the same.

AT a recent meeting of the Epsom Rural District Council the Local Government Board forwarded the draft of its Provisional Order to enable the Council to put in force the compulsory powers of the Lands Clauses Acts for the purpose of acquiring, other than by agreement, certain land required for the disposal of the sewage of the parish of Cobham. The draft was approved.

THE parishioners of Newmarket are in arms against the action of the Holywell Rural District Council in providing them with a drain, and having met at a parish meeting, it was decided—first, that as many parishioners as possible should attend the next meeting of the District Council by way of protest; secondly, that the parishioners are determined not to pay any part of the expense; and, thirdly, that the drain be removed at once, it being pointed out that it drained into and polluted a pool which was used for drinking by the cattle of the farmers.

AT a recent meeting of the Swinton and Pendlebury Urban District Council it was decided to again retain the services of Mr. T. S. McCallum, of Manchester, in connection with the Pendlebury sewage works. It is proposed now to erect sludge-pressing machinery, &c. The Council's Surveyor, Mr. H. Entwistle, is also preparing an important scheme in connectlon with the separation of the surface water from the sewage.

THE Burgh Commissioners of Moffatt have adopted the Dibdin system, as reported on by Mr. Niven, C.E., Glasgow, for the purification of the town sewage before it is discharged into the river Annan. The Commissioners contemplate placing the works on the farm of Oakrigg. It is proposed to provide an installation capable of dealing with 200,000 gallons in twenty-four hours, which will necessitate an area of about 670 square yards for tank and filter accommodation. The total estimated cost of introducing this system of sewage purification is £2350.

AT a recent meeting of the Wishaw Commissioners, on the recommendation of the Sanitary Committee it was agreed to lease the fields in front of Wilson's-rows, where, owing to a large subsidence in Marshall-street, caused by underground workings, a sewage line is presently running through, and sub-let them with a provision in agreement to safeguard the Commissioners. Offers were opened for furnishing and erecting a 300-yard line of red pine troughs in connection with sewage purification at Carbarns, and that of D. and J. Nimmo, Main-street, was accepted. It was agreed to accept the tender of Thos. Crawford and Son, Wishaw, for the drainage of East Thornlie-street, and streets adjoining.

AT the last meeting of the West Riding Rivers Board the chairman of the Domestic Sewage and Solid Refuse Committee stated that a letter had been received from the Leeds Corporation explaining, in reply to a question as to the disposal of the sewage of Leeds, that their important and costly experiments in connection with bacterial treatment were not yet sufficiently complete and conclusive to enable the Committee to base upon them a general scheme. The experiments, conducted under the supervision of Mr. W. J. Dibdin, were in a way unique, for, so far as was known, they were the first experiments in bacteria beds of crude sewage containing a great variety and volume of trade effluents. Briefly, the results so far were very satisfactory in regard to the quality of the final effluent, in which fish had been living now for over two months, but at present the Committee were obliged to suspend their judgment as to the ultimate issue of the experiments.

RELATIVE COST OF WORKS OF SEWAGE DISPOSAL.

(*To the Editor of* THE SANITARY RECORD.)

SIR,—The Sutton rejoinder in your issue of 11th ult. to the Exeter broadside in your issue of Feb. 18th is very interesting to experts who can balance them. To all who cannot do so Sutton's conclusion that the differences are small as compared with the glaring defects in the costly "precipitation processes in vogue," and that both Exeter and Sutton processes are a "long way ahead of any hitherto known process of sewage treatment," is the truth which should be rubbed into all the wooden heads of the country, beginning with those of the Loca Government Board. The latter having been bowled over by their inquiry at Exeter four months ago, are now taking refuge under a new Royal Commission. The old one—thirty years old now—decreed that land was the only possible filter, and this poor board—not daring to call their souls their own—have got a new commission to authorise them to say that clinker is infinitely cheaper and more efficient than land, and thus officially to sign the death warrant of the quacks and charlatans who by precipitation processes of sorts have fattened in the interim on the helpless ignorance of Local Authorities.

No greater scandal can be proven against this generation than the supineness and incapacity of "the powers that be" in dealing with the problem of sewage disposal.

However, that is by the way; the real issue between the two new processes is far simpler than appears from the correspondence cited. It resolves itself into two parts, viz.:—Covered tank *v.* open coarse filter, and automatic gear *v.* labour, to secure intermittent use of the final filters which are common to both processes. On the first point the covering of the tank is an extra which may be of the simplest kind—it is neither necessary nor desirable to make the tank *air* tight. The exclusion of rain, dust, leaves, &c., and protection from frost is all that is required to secure bacterial liquefaction of sewage solids. That simple cover dispenses with screens, and the daily clearing of screens, which is a horrid nuisance in private installations (have known a man resign his post rather than do it), and it dispenses also with the distributing channels, and the clearing of them in and the trenching of coarse filters. That the covered tank requires no fall is an important advantage too. To my mind it is absurd to compare a covered tank which works practically *without* attention with screens and a channelled filter which would choke if neglected for a day; and Dibdin has greatly wronged himself in not frankly recognising the immense superiority of the liquefying tank over the liquefying filter as regards cost of construction plus maintenance, assuming that their effluents are equally good. Probably he felt himself driven to devise some means of utilising the liquefying bacteria without royalty, but he might fairly question the claim for royalty on such tanks. I know of many that were constructed long before the septic was heard of.

Small water-tight covered cesspools—liquefying solids perennially without attention from year's end to year's end—that is the whole matter. Notwithstanding this, for having so gallantly fought and won the public battle, having slain the chemical precipitator, and delivered the country from the sludge incubus, Cameron has fairly earned a baronetcy and a grant of public money adequate to duly maintain the honour.

He should also be empowered to nominate for knighthood, say, a dozen of the Exeter folks who have supported him in the battle.

At such price the services already rendered to the public would be undeniably cheap. Further, he should be appointed Chief of the Engineering Department of the Local Government Board, which in turn should be impeached for criminal neglect of duty. Dibdin, too, should be baronetised for his nitrifying beds on the Thames.

We now come to the only other point at issue, viz., automatic gear *v.* labour to secure intermittent use of the final filters.

The gear is good, and it will pay to pay any royalty for it which is less than the cost of labour for hand intermission, until a continuous filter crops up and dispenses with both, but it is ridiculous for the patentees to base the royalty on the cost of the tank and filters; *first*, because that varies greatly—boarded *v.* cement cover for tank—filter capacity (or quality of effluent) varying with outfall, which may well double or treble the cost of the same set of gearing for two places; and *second*, because neither tank nor filters are subject to royalty if I am right.

Let the gear be put up in sets to suit varying numbers of filters, and be charged at twice or thrice the cost, then they will be introduced everywhere. No doubt the patentees will be content with this if the Government recognises and recompenses their services to the commonwealth as above indicated. —Yours faithfully, SANITAS.

SEWAGE PURIFICATION.
